

# A Cell-Based Multiphase Interleaving Buck Converter with Bypass Capacitors

T. Taufik, R. Prasetyo, D. Dolan and D. Garinto

**Abstract**—Today's Voltage Regulator Modules (VRMs) face increasing design challenges as the number of transistors in microprocessors increases per Moore's Law. These challenges have recently become even more demanding as microprocessors operate at sub voltage range at significantly high current. This paper presents a new multiphase topology with cell configuration for improved performance in low voltage and high current applications. A lab scale hardware prototype of the new topology was design and constructed. Laboratory tests were performed on the proposed converter and compared with a commercially available VRM. Results from the proposed topology exhibit improved performance compared to the commercially available counterpart.

**Keywords**—Voltage Regulator Modules, dc-dc converters, power electronics.

## I. INTRODUCTION

VOLTAGE regulator module (VRM) is a dc-dc converter that provides the necessary power into a microprocessor. This converter can be either soldered on to the motherboard or it could be provided by a module attached to the board. Design specifications of VRMs are typically determined by microprocessor's manufacturers. For example, Intel has established design guidelines for VRM called Intel VRM11.0. Today's VRMs are based on a topology called the multiphase synchronous buck converter as shown in Figure 1 [1,2,3,4,5].

One important operating parameter in the multiphase buck converter topology is called the duty cycle  $D$ . For buck converter, the ideal duty cycle is the ratio of the output voltage and input voltage. The basic multiphase buck converter worked very well in earlier VRMs where 5V was required at the input. However, as microprocessor technologies advances, new challenges in VRM design have arisen [6]. For example, today's microprocessors for desktop computers, workstations, and low-end servers, require VRMs to operate with 12V input. Laptops required VRMs to directly step down the battery charger voltage of 16-24V down to the microprocessor voltage of 1.5V. Future microprocessors are also expected to supply

voltage to decrease below 1V in order to further reduce power dissipation [6]. This means that for these applications, the VRM and hence the multiphase buck converter will have to operate at very small duty cycles. The small duty cycle further translates into an increase in conduction loss of the multiphase buck converter which gets worsen as the required output power is increased [7].

Fig. 1 Multiphase synchronous buck topology

Another challenge comes in the form of transient speed. Since further microprocessors call for fast operation, hence the VRM consequently is required to keep up with the speed. For dc-dc converters, this means the switching frequency has to be increased. However, when the switching frequency is increased, then more switching loss will occur at the top MOSFET as well as an increase in MOSFET's gate drive and body diode losses. Consequently, efficiency will drop to less than 80% when switching frequency is increased into multi-MHz [3].

Yet another challenge when designing today's VRMs would be the tradeoff between efficiency and transient response of the converter. In order to increase inductor current slew rate, a small inductance is required, but the small inductance also increases peak to peak current ripple; thus reducing the overall efficiency of the converter itself. This is true since an increase in the peak to peak current ripple translates to an increase in the top switch turn-off loss [7].

In this paper, a new multiphase buck topology that addresses the aforementioned technical challenges by utilizing cell configuration and storage components will be presented. A hardware prototype was built and tests were conducted to

assess its performance against those obtained from a commercially available VRM with comparable output power.

## II. THE PROPOSED NEW TOPOLOGY

Figure 2 depicts the basic schematic of the proposed multiphase interleaving buck converter. There are two major modifications from the basic multiphase. First, the topology comprises of cells each consisting of two buck converters. To operate the converter, a minimum of two cells will be required. Doing so will enable us to interleave individual bucks with proper sequencing of their control signals. For example, in the basic 4 phase multiphase buck converter, the control signal sequence is Phase 1, 3, 2, 4. In the proposed topology, the sequence is changed to Phase 1, 2, 3, 4 hence allowing the interleaving of buck converters to occur. This results in improved thermal distribution and hence less heat-sinking requirement and better efficiency.

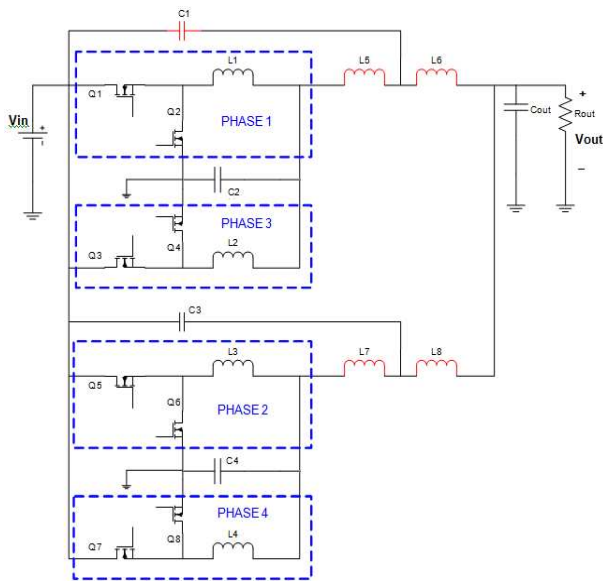

Fig. 2 Proposed multiphase interleaved buck topology

Secondly, the proposed multiphase synchronous buck topology incorporates additional storage components that serve different purposes. For example, the additional output inductors (L5, L6, L7, L8) are placed to minimize output current ripple useful in reducing rms loss at the output capacitor (Cout) or from the copper loss of the inductors themselves, including from the main inductors (L1, L2, L3, L4). However, these inductors will consequently slow down the transient response which may be overcome by increasing the switching frequency of the converter, and by adding the input-output bypass capacitor in each cell (C1 and C3) for energy support required by the load during transient.

To illustrate interleaving operation, Figure 3 shows the timing diagram of control signals to the four bucks. In an N-phase multiphase, the duty cycle for each phase is equal to  $V_{out}/V_{in}$  and it is the same for all phases due to parallel configuration. A phase shift should therefore be implemented between the timing signals of the top switch from the first and second phases. The value of the phase shift follows the

equation  $360^\circ/N$  where N is number of phases. For example, in the 2-phase case, the amount of phase shift will be  $360^\circ/2 = 180^\circ$ .

Fig. 3 Timing diagram for Top MOSFETs

Figure 4 shows inductor current in each time segment from  $T_0$  to  $T_8$ . IL1 corresponds to inductor current flowing through inductor L1, IL2 through inductor L2, and so on, while Iout is the output current. The linear ramp-up of each inductor current signifies the charging of inductor, while linear ramp-down depicts the discharging of inductor. One advantage of multiphase is exhibited on the output current. Due to the ripple cancellation effect, the output current possesses 1/4 of the peak to peak ripple and 4 times the frequency of main inductor current. These provide the benefits of reducing rms loss, fast transient time, and small output filtering requirement.

Fig. 4 Inductor currents for phases (a) 1&3, (b) phases 2&4, (c) auxiliary inductor currents, and (d) output current

Referring to times  $T_0$  to  $T_8$  as shown in Figure 4, during interval  $T_0$  to  $T_1$ , Q1 turns on. As illustrated in Figure 5(a), current flows from  $V_{in}$  to output through Q1, L1, L5 and L6. In this case the current through L1, L5, and L6 increases linearly since the input and output voltages are both fixed at  $V_{in}$  and  $V_{out}$  respectively. At the same time, energy stored in

C1 is being discharged through Q1 and L1, while the energy stored in C2 is also being discharged through L5 and L6. Meanwhile, L2 is also discharged through L5 and L6.

At time  $T_1$  switch Q1 is turned off, and switch Q2 is turned on as illustrated in Figure 5(b). During  $T_1$  to  $T_2$ , the energy stored in L1 together with energy left in L2 is now being used to charge C2. Energy stored previously in L5 and L6 flows to output. The energy in C1 would be charged by the input during this time.

The next transition from  $T_2$  to  $T_3$  is depicted in Figure 5(c). Switch Q5 is turned on, and the same sequence of energy flow occurs as the one described in the first phase (from  $T_0$  to  $T_2$ ). Here, C3 replaces C1, C4 replaces C2, L3 replaces L1, L7 replaces L5, and L8 replaces L6. The same cycle will also repeat for phase 3 (Q3 and Q4) and phase 4 (Q7 and Q8).

### III. HARDWARE RESULTS

The proposed topology was put in test by building its hardware prototype. Prior to developing the hardware, a set of design objectives were chosen as listed in Table I.

TABLE I  
DESIGN REQUIREMENTS FOR THE PROPOSED CONVERTER

Parameter	Requirements
Nominal Input Voltage	12 V
Nominal Output Voltage	1 V
Maximum output current	40 A
Inductor ripple current	10 % of Maximum Phase Current
Output Voltage Ripple	< 15 mV <sub>p-p</sub>
Switching Frequency	500 kHz per phase
Load Regulation	< 2 %
Line Regulation	< 5 %
Efficiency	> 80 % at Full Load

Based on these design requirements, each component in the proposed was selected. In addition, loss analysis was also performed over load variations. Table II summarizes components that contribute to major losses in the proposed multiphase buck topology calculated at full load condition.

TABLE II  
POWER LOSS ON EACH DEVICE AT 40A LOAD CURRENT

Components	Power Loss (W)
Input Capacitor	0.222
Top MOSFET	1.164
Bottom MOSFET	3.412
Main Inductor	1.252
Auxiliary Inductor	0.272

Figure 6 shows the final hardware prototype of a 4 phase version of the proposed topology. Each phase is running at 500 kHz switching frequency which makes both input and output components to have frequency component of  $4 \times 500$  kHz = 2 MHz. The prototype was done on a multi-layer pcb,

approximately 2.5 in. x 2.5 in. The top layer was dedicated for all the controller chips while the bottom layer was used specifically for the power components (inductors, MOSFETs). Laboratory tests were then conducted on the prototype to assess its performance on several standard dc-dc operating parameters. Results were then compared to those obtained from a commercially available VRM.

Fig. 6 Prototype circuit board of the proposed converter (a) top layer (b) bottom layer

First, the output voltage ripple was observed to be approximately 8.2mV at full load, see Figure 7. This peak to peak ripple is considerably less compared to that of the commercially available VRMs (typically 40-50mV). However, the output voltage of the proposed converter appears to have so much high frequency noise on top its actual peak to peak ripple. This may be explained by the fact that the frequency component of the output voltage is relatively high at 2 MHz (4 x 500 kHz). Hence, a better layout and/or filtering will be necessary to suppress this high frequency noise.

Next, load transient tests were performed to see how fast the proposed converter recovers upon a step change in the load. Figure 8 shows both step up and step down responses of the converter in terms of its output voltage.

The step up and step down responses as shown in Figure 8 were measured to be 136 us and 160 us respectively. This is comparable to the 150 us step responses measured in the commercially available VRM.

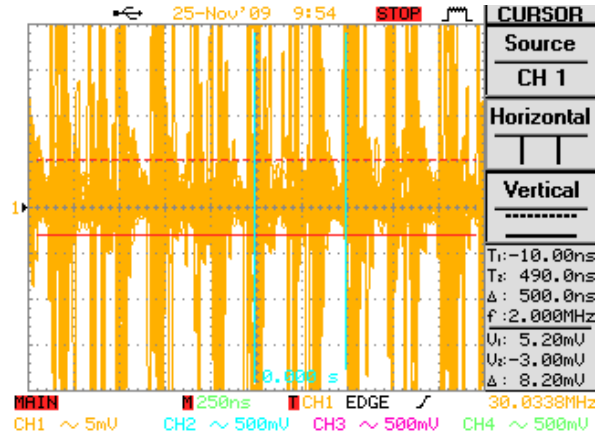

Fig. 7 Output voltage ripple at full load

Fig. 8 Step changes in load current (bottom) and the responses on the output voltage (top)

Table III lists results of measurements taken when the load was increased by 10% steps. The data were then used to calculate both load and line regulations as follows:

$$\text{Line Regulation} = \frac{V_{OUT(High Input)} - V_{OUT(Low Input)}}{V_{OUT(no min al)}} \times 100\%$$

$$= \frac{1.006 V - 1.006 V}{1.006} \times 100\% = 0\%$$

$$\text{Load Regulation} = \frac{V_{OUT(No Load)} - V_{OUT(Full)}}{V_{OUT(Full)}} \times 100\%$$

$$= \frac{1.006 V - 1.006 V}{1.006} \times 100\% = 0\%$$

When compared against the commercially available VRM, the proposed topology has a comparable line regulation (close to 0%) but it is superior in its load regulation (close to 0% as compared to 0.8%).

TABLE III  
MEASUREMENT DATA OF THE PROPOSED TOPOLOGY

Load (%)	Vin(V)	Iin(A)	Pin(W)	Vout(V)	Iout(A)	Pout(W)	Efficiency (%)
0	12.006	0.267	3.210	1.006	0.01	0.010	0.31
10	12.006	0.731	8.773	1.006	5	5.030	57.34
20	12.007	1.186	14.235	1.006	10	10.060	70.67
30	12.006	1.648	19.786	1.006	15	15.090	76.27
40	12.004	2.119	25.430	1.006	20	20.120	79.12
50	12.003	2.599	31.191	1.006	25	25.150	80.63
60	11.992	3.092	37.077	1.006	30	30.180	81.40
70	12.004	3.593	43.132	1.006	35	35.210	81.63
80	12.004	4.110	49.338	1.006	40	40.240	81.56
90	11.996	4.644	55.706	1.006	45	45.270	81.27
100	12.004	5.189	62.294	1.006	50	50.300	80.75

Finally, from Table III the overall efficiency of the proposed converter was generated as shown in Figure 9. The efficiency tracks the 80% line beginning approximately at 40% load. At full load, the efficiency of the proposed converter is 80.75% which meets the design objective and is slightly larger than that measured from the commercially available VRM (80%).

Fig. 9 Efficiency of the proposed converter

#### IV. CONCLUSION

With the increasing demand for power in today's microprocessors, the design of VRM will become more challenging than ever before. Conventional or basic topology used in most commercially available VRMs will not be sufficient to satisfy the thirst of power and speed of today's and future microprocessors. The proposed topology presented in this paper is aimed to address this issue. The use of cell configuration has demonstrated the effectiveness in interleaving a multiphase topology. Furthermore, the strategic placements of bypass capacitors have been shown to suppress the output voltage level to a minimum value which is critical in sub-volt applications. Further lab measurements on the hardware prototype exhibit promising results of its potential. Although the results are overall comparable to those obtained from a commercially available VRM, two particular results are worth noting. First, load regulation of the proposed converter was measured to be practically 0% which is a significant improvement from the one measured on the commercially available VRM. Load regulation becomes even crucial when output current is much higher than the 40A that was tested on

this prototype. Thus, from this aspect, the proposed converter has shown its great potential for use in very high output current applications with very tight load regulation such as those expected in future microprocessors.

Secondly, the efficiency plot of the proposed converter was actually sloping down gradually after the full load. This is much different from that measured on the commercially available VRM in which the efficiency dives down relatively faster. This means, again for much higher output current applications such as those expected in future microprocessors, the proposed converter exhibits a great potential for use in future VRMs.
