

Electric Field and Potential Distributions along Surface of Silicone Rubber Polymer Insulators Using Finite Element Method

B. Marungsri, W. Onchantuek, and A. Oonsivilai

Abstract—This paper presents the simulation the results of electric field and potential distributions along surface of silicone rubber polymer insulators. Near the same leakage distance subjected to 15 kV in 50 cycle salt fog ageing test, alternate sheds silicone rubber polymer insulator showed better contamination performance than straight sheds silicone rubber polymer insulator. Severe surface ageing was observed on the straight sheds insulator. The objective of this work is to elucidate that electric field distribution along straight sheds insulator higher than alternate shed insulator in salt fog ageing test. Finite element method (FEM) is adopted for this work. The simulation results confirmed the experimental data, as well.

Keywords—Electric field distribution, potential distribution, silicone rubber polymer insulator, finite element method.

I. INTRODUCTION

POLYMER insulators, which are being used increasingly for outdoor applications, have better characteristics than porcelain and glass types: they have better contamination performance due to their surface hydrophobicity, lighter, possess higher impact strength, and so on. However, since polymer insulators are made of organic materials, deterioration through ageing is unavoidable. Hence, ageing deterioration is a primary concern in the performance of polymer insulators. Artificial salt fog ageing tests have been most widely conducted on simple plates, rods, and small actual insulators for evaluating the anti-tracking and/or anti-erosion performance of housing materials for polymer insulators [1–7].

In previous work, salt fog ageing test have been conducted on specimens having different configurations [8]. Although tested specimens having the same leakage distance and made of the same material, obviously degree of surface ageing on tested specimens was obtained. Fully results and discussions are found in [8]. However, briefly results are illustrated in Section II.

In order to elucidate the effect of specimen configuration in the view point of electric field and potential distributions

along the specimen surface, Finite Element Method (FEM) is adopted as mathematical tool for simulation electric field and potential distributions.

II. ARTIFICIAL SALT FOG AGEING TEST RESULTS

Two insulator-type specimens, having straight and alternate sheds, were prepared as shown in Fig. 1. All the specimens were made of high-temperature vulcanized silicone rubber (HTV SiR) with alumina trihydrate (ATH: $\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) filler contents of 50 parts per 100 by weight (pph). The insulator-type specimens were prepared by molding HTV SiR onto the FRP rods. Molding lines or parting lines were found on these insulator-type specimens. Two pieces of each specimen type were used in this investigation. All specimen surfaces were cleaned by ethyl alcohol 24 hours before starting the test.

Fig. 1 Test Specimens

All specimens were hung vertically in a plastic chamber as shown in Fig. 2 and were tested together under the test conditions shown in Table I. The cyclic salt fog ageing test was conducted by injecting salt fog into the chamber for 8 hours and stopping it for 16 hours every day under AC 15kV. The salt fog, with a salinity of $800 \mu\text{S}/\text{cm}$ and an injection rate of $0.5 \text{ l/hr}/\text{m}^3$, was generated using an ultrasonic humidifier and was injected from the top of the test chamber as shown in Fig. 2. Leakage currents were continuously measured on individual specimens.

W. Onchantuek and A. Oonsivilai are with Suranaree University of Technology, Nakhon Ratchasima, 30000, Thailand.

TABLE I
TEST CONDITIONS

Test Chamber	1590 mm×1560 mm ×1330 ^{II} mm, (2m ³)
Test Voltage	AC 15 kV, Continuously Applied
Voltage Stress	60 V/mm for rod type, 51.3 V/mm for insulator types
Salt Fog	Generation Ultrasonic Humidifier (Model WM – B NB 1000)
	Injection Rate 0.5 l / hr / m ³
	Conductivity 800 μS / cm
Test Sequence in 1 Cycle (24 hours)	Salt fog injected for 8 hours and stopped for 16 hours

Fig. 2 Test Arrangement

During 50 test cycle of salt fog ageing test, stronger surface discharges were observed on the specimen having straight sheds comparing with the specimen having alternate sheds although all specimens having the same leakage distance and made of the same materials. The observation result is illustrated in Fig. 3. After 50 test cycles, severe surface ageing was observed on the trunk between sheds of specimens having straight shed comparing with the specimen having alternate sheds, as shown in Fig. 4. Considering the results, the assumption is electric field distribution along the specimen having straight shed higher than the specimen having alternated sheds.

III. NUMERICAL EXPERIMENT

A. Equations for Electric Field and Potential Distributions Calculation

Simply way for electric field distribution calculation is calculate electric potential distribution. Then, electric field distribution is calculated by minus gradient of electric potential distribution. Due to electrostatic field distribution, electric field distribution can be written as follows [9]:

$$E = -\nabla V \quad (1)$$

From Maxwell's equation

$$\nabla E = \frac{\rho}{\epsilon} \quad (2)$$

where ρ is resistivity Ω/m ,

ϵ is dielectric constant of dielectric material

($\epsilon = \epsilon_0 \epsilon_r$)

ϵ_0 is air or space dielectric constant (8.854×10^{-12}

F/m)

ϵ_r is relative dielectric constant of dielectric

material

Place equation (1) in equation (2) obtained Poisson's equation.

$$\nabla \epsilon \nabla V = -\rho \quad (3)$$

Without space charge $\rho = 0$, Poisson's equation becomes

Laplace's equation.

$$\nabla \epsilon \nabla V = 0 \quad (4)$$

B. Equations for FEM Analysis of the Electric Field Distribution

The finite element method is one of the numerical analysis methods based on the variation approach and has been widely used in electric and magnetic field analyses since the late 1970s. Supposing that the domain under consideration does not contain any space and surface charges, the two-dimensional functional $F(u)$ in the Cartesian system of coordinates can be written as follows[10]:

$$F(u) = \frac{1}{2} \int_D \left[\varepsilon_x \left(\frac{du}{dx} \right)^2 + \varepsilon_y \left(\frac{du}{dy} \right)^2 \right] dx dy \quad (5)$$

where ε_x and ε_y are the x - and y -components of the dielectric constant in the Cartesian system of coordinates and u is the electric potential. In the case of isotropic permittivity distribution ($\varepsilon = \varepsilon_x = \varepsilon_y$), Equation (5) can be rewritten as

$$F(u) = \frac{1}{2} \int_D \varepsilon \left[\left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right] dx dy \quad (6)$$

If the effect of dielectric loss on the electric field distribution is considered, the complex functional $F(u)$ should be taken as

$$F(u) = \frac{1}{2} \int_D \omega \varepsilon_0 (\varepsilon - j \varepsilon \cdot \tan \delta) \left[\left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right] dx dy \quad (7)$$

where ω is angular frequency, ε_0 is the permittivity of free space (8.85×10^{-12} F/m), $\tan \delta$ is tangent of the dielectric loss angle, and u^* is the complex potential.

Inside each sub-domain D_e , a linear variation of the electric potential is assumed, i.e.

$$u_e(x, y) = \alpha_{e1} + \alpha_{e2}x + \alpha_{e3}y \quad ; (e = 1, 2, 3, \dots, ne) \quad (8)$$

where $u_e(x, y)$ is the electric potential of any arbitrary point inside each sub-domain D_e , α_{e1} , α_{e2} and α_{e3} represent the computational coefficients for a triangle element e , ne is the total number of triangle elements.

The calculation of the electric potential at every knot in the total network composed of many triangle elements was carried out by minimizing the function $F(u)$, that is,

$$\frac{\partial F(u_i)}{\partial u_i} = 0 \quad ; i = 1, 2, \dots, np \quad (9)$$

where np stands for the total number of knots in the network.

Then we can get a metrical expression

$$[S_{ji}] \{u_i\} = \{T_j\} \quad i, j = 1, 2, \dots, np \quad (10)$$

where $[S_{ji}]$ is the matrix of coefficients, $\{u_i\}$ is the matrix vector of unknown values of the potential at the knots and $\{T_j\}$ is the metrical vector of free terms. The metrical equation (10) can be solved using various methods, including the Gauss-Seidel iterative method.

C. Implementation for FEM Analysis

The basic design of a polymer insulator is as follows; A fibre reinforced plastic (FRP) core having relative dielectric constant 7.1, attached with two metal fittings, is used as the load bearing structure. Weather sheds made of HTV silicone rubber having relative dielectric constant 4.3 are installed outside the FRP core. Surrounding of the insulator is air having relative dielectric constant 1.0. AC 15 kV is energized on the lower electrode while the upper electrode connected with ground. Two dimensions of the two type polymer insulators for FEM analysis are shown in Fig. 5.

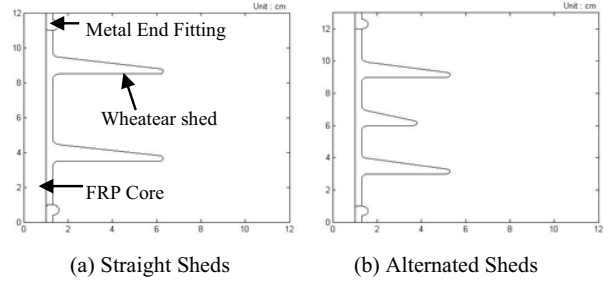

Fig. 5 Two dimension of the two type polymer insulators for FEM analysis

The whole problem domain in Fig. 5 is fictitiously divided into small triangular areas called *domain*. The potential, which is unknown throughout the problem domain, is approximated in each of these elements in terms of the potential in their vertices called *nodes*. Details of Finite Element discretization are found in [12]. The most common form of approximation solution for the voltage within an element is a polynomial approximation. PDE Tool in MATLAB is used for finite element discretization. The obtaining results are 1,653 nodes and 3,180 elements for straight sheds type insulator and 2,086 nodes and 4,030 elements for alternate sheds type insulator, respectively. The obtaining results are shown in Fig. 6

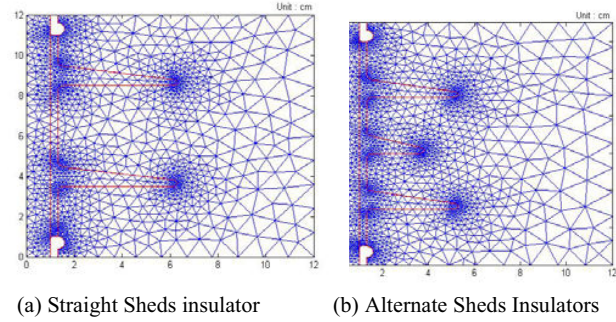

Fig. 6 Finite element discretization results

IV. SIMULATION RESULTS AND DISCUSSIONS

Clean and contamination conditions are simulated in this study. Potential Distribution results are shown in Fig. 7 and electric field distribution are shown in Fig. 8. Although nonlinear potential distribution along leakage distance of the two type specimens, more nonlinear can be seen on the straight sheds specimen comparing with the alternate shed specimen, as shown in Fig. 9. In spite of clean condition, electric field distribution on the straight sheds specimen is higher than the alternate sheds specimen.

Contamination condition is simulated by place water droplets on the two type insulator surfaces as shown in Fig. 10 and Fig. 12. The simulation results of electric field and potential distributions are illustrated in Fig. 11 and Fig. 13, respectively.

Fig. 12 Alternate Sheds Insulator with Water Droplets on the Surface

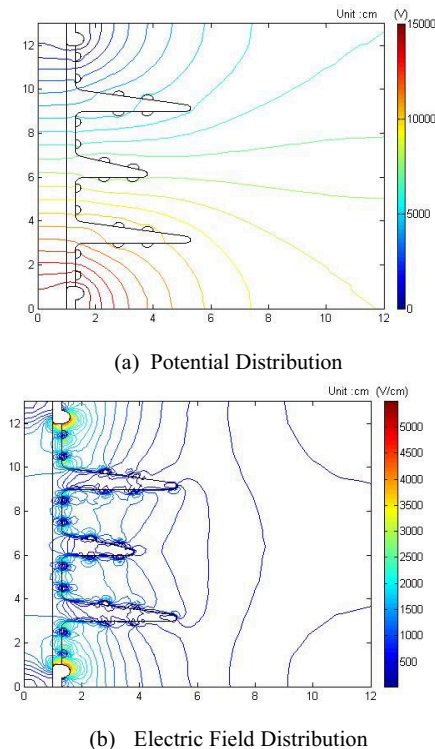

Fig. 13 Alternate Sheds Insulator with Water Droplets on the Surface

Fig. 14 Comparison of Potential Distribution under Contamination Condition

Comparison of potential distribution along leakage distance under contamination condition is illustrated in Fig. 14. Under

contamination condition, higher electric field distribution and more nonlinear potential distribution obtained from the straight sheds insulator comparing with the alternate sheds insulators. The simulation results are agreed with the experimental results. Higher magnitude of electric field caused more electric discharge on the insulator surface. More discharge activities caused severe surface damages.

V. CONCLUSION

Higher magnitude of electric field distribution and more nonlinear potential distributions on the straight sheds insulator comparing with the alternate shed insulators obtained from the simulation results by using Finite Element Method. The simulation results are agreed with the experimental results. In spite of the same leakage distance and the same material, different degree of surface aging obtained from polymer insulator having different configurations.
