

# A Study of Thermal Convection in Two Porous Layers Governed by Brinkman's Model in Upper Layer and Darcy's Model in Lower Layer

M. S. Al-Qurashi

**Abstract**—This work examines thermal convection in two porous layers. Flow in the upper layer is governed by Brinkman's equations model and in the lower layer is governed by Darcy's model. Legendre polynomials are used to obtain numerical solution when the lower layer is heated from below.

**Keywords**—Brinkman's law, Darcy's law, porous layers, Legendre polynomials, the Oberbeck-Boussineq approximation.

## I. INTRODUCTION

THERMAL instability theory has attracted considerable interest and has been recognized as a problem of fundamental importance in many fields of fluid dynamics. The earliest experiments to demonstrate the onset of thermal instability in fluids are those of Bernard's [1, 2]. Benard worked with very thin layers of an incompressible viscous fluid standing on a levelled metallic plate maintained at a constant temperature. The upper surface was usually free and, being in contact with the air, was at a lower temperature. In his experiments, Benard deduced that a certain critical adverse temperature gradient must be exceeded before instability can set in. The instability of a layer of fluid heated from below and subjected to Coriolis forces has been studied by Chandrasekhar [3, 4] for a stationary and overstability case. He showed that the presence of these forces usually has the effect of inhibiting the onset of thermal convection. Nield [5] considered the onset of salt-finger convection in a porous layer. Taunton et al. [6] considered the thermohaline instability and salt-finger in a porous medium and solved the boundary value problem. Sun [7] was the first to consider such a problem, and he used a shooting method to solve the linear stability equations. Sun [7] and Nield [8] used Darcy's law in formulating the equations of porous layer. In Darcy's law of motion in porous mediums, the Darcy resistance term took the place of the Navier-stokes viscosity term, while in the modified Darcy's law (Brinkman model), suggested by Brinkman [9], the Navier- stokes viscosity term still exists. Chen & Chen [10] considered the multi-layer problem when the above layer is heated and salted from above, and the solution of the problem is obtained using a shooting method. Lindsay & Ogden [11] worked in the implementation of spectral methods resistant to the generation of spurious eigenvalues. Lamb [12] used expansion of Chebyshev

polynomials to investigate an eigenvalue problem arising from a model discussing a finitely conducting inner core of the earth on magnetically driven instability. Bukhari [13] studied the effects of surface-tension in a layer of conducting fluid with an imposed magnetic field and obtained results when the free surface is deformable and non-deformable. He solved that by using Chebyshev spectral method, and thus obtained some different results from that of Chen & Chen [10]. Straughan [14] studied the thermal convection in fluid layer overlying a porous layer and considered the problem of lower layer heated from below and surface tension driven on the free top boundary of upper layer. In [15], he also dealt with the same problem considering the ratio depth of the relative layer and investigated the effect of the variation of relevant fluid and porous material properties. Allehiany [16] studied Benard convection in a horizontal porous layer permeated by a conducting fluid in the presence of magnetic field and coriolis forces. Al-Qurashi & Bukhari [17] studied the salt finger convection in a horizontal porous layer superposed by a fluid layer affected by rotation and vertical linear magnetic field on both layers. The solution is obtained using Legendre polynomials when the heat and the salt concentration affected from above.

## II. MATH

Let  $L_1$  and  $L_2$  be two horizontal porous layers such that the top of the layer  $L_2$  touches the bottom of the layer  $L_1$ . The plane interface between the two layers is  $x_3 = 0$ , the upper boundary of  $L_1$  is  $x_3 = d_B$  and the lower boundary of  $L_2$  is  $x_3 = -d_D$ . We suppose that the two layers occupied by a porous medium permeated by an incompressible thermally and electrically conducting viscous fluid. The fluid flow in the porous layer  $L_2$  is governed by Darcy's law, whereas the fluid flow in the porous layer  $L_1$  is governed by Brinkman's law. Gravity  $\mathbf{g}$  acts in the negative direction of  $x_3$  (Fig. 1).

Fig. 1 Schematic representation of the physical configuration

Convection is driven by temperature dependence of the fluid density and damped by viscosity. The Oberbeck-Boussineq approximation is used as the density of fluid is constant everywhere except in the body force term where the density is linearly proportional to temperature, i.e

$$\rho = \rho_0 [1 - \alpha(T - T_0)] \tag{1}$$

the governing equations of the porous layer  $L_1$  are

$$\frac{1}{\phi_B} \frac{\partial V_B}{\partial t} = -\nabla \frac{P_B}{\rho_0} - \frac{\mu}{K_B} V_B + \nu \nabla^2 V_B - g [1 - \alpha(T_B - T_0)]$$

$$\frac{\partial T_B}{\partial t} + V_B \cdot \nabla T_B = k_B \nabla^2 T_B, \tag{2}$$

and the governing equations of the porous layer  $L_2$  are

$$\frac{1}{\phi_D} \frac{\partial V_D}{\partial t} = -\nabla \frac{P_D}{\rho_0} - \frac{\mu}{K_D} V_D - g [1 - \alpha(T_D - T_0)]$$

$$\frac{\partial T_D}{\partial t} + V_D \cdot \nabla T_D = k_D \nabla^2 T_D, \tag{3}$$

where  $p_D, p_m$  are the pressure of the porous layers  $L_1$  and  $L_2$  respectively,  $V_D, V_B$  are seepage velocity of the porous layers  $L_1$  and  $L_2$  respectively,  $T_D, T_B$  are the Kelvin temperature of the porous layers  $L_1$  and  $L_2$  respectively,  $k_D, k_B$  are the thermal and overall thermal conductivity of the porous layers  $L_1$  and  $L_2$  respectively,  $\mu$  is the viscosity,  $K_D, K_B$  is the permeability of the porous layers  $L_1$  and  $L_2$  respectively,  $\phi_D, \phi_B$  is its porosity of the porous layers  $L_1$  and  $L_2$  respectively.

*A. The boundary Conditions*

Suppose that  $x_3 = d_B$  is rigid and maintained at constant temperature  $T_u$ , and  $x_3 = -d_D$  is rigid and maintained at constant temperature  $T_l$ , then the boundary conditions can be written as:

$$w_B(d_B) = 0, \quad \frac{\partial w_B}{\partial x_3}(d_B) = 0, \quad T_B(d_B) = T_l, \tag{4}$$

on the upper boundary, and

$$w_D(-d_D) = 0, \quad \frac{\partial w_D}{\partial x_3}(-d_D) = 0, \quad T_D(-d_D) = T_u, \tag{5}$$

on the lower boundary, where  $w_B$  and  $w_D$  are the normal axial velocity components of the porous layers  $L_1$  and  $L_2$  respectively. The boundary conditions on the interface plane  $x_3 = 0$  are based on the assumption that temperature, heat flux, normal fluid velocity and normal stress tensor are continuous so that

$$T_B(0) = T_D(0), \quad k_B \frac{\partial T_B}{\partial x_3}(0) = k_D \frac{\partial T_D}{\partial x_3}(0),$$

$$w_B(0) = w_D(0), \quad -p_B(0) + 2\mu \frac{\partial w_B}{\partial x_3}(0) = -p_D(0), \tag{6}$$

Equations (2) and (3) have an equilibrium solution satisfying the boundary conditions (4)-(6) on the form

$$V_B = 0, \quad V_D = 0,$$

$$-\nabla P_B + \rho_f g = 0, \quad -\nabla P_D + \rho_f g = 0, \tag{7}$$

$$\nabla^2 T_D = \nabla^2 T_B = 0,$$

and with the boundary conditions

$$T_B(d_B) = T_u, \quad T_D(-d_D) = T_l, \tag{8}$$

and the interface conditions

$$T_B(0) = T_D(0), \quad k_B \frac{\partial T_B}{\partial x_3}(0) = k_D \frac{\partial T_D}{\partial x_3}(0), \quad P_B(0) = P_D(0), \tag{9}$$

the equilibrium temperature field, hydrostatic pressure and salt concentration in the fluid layer and porous medium layer are respectively:

$$T_B = T_0 - (T_0 - T_u) \frac{x_3}{d_B}, \quad P_B = P_B(x_3), \quad 0 \leq x_3 \leq d_B,$$

$$T_D = T_0 - (T_l - T_0) \frac{x_3}{d_D}, \quad P_D = P_D(x_3), \quad -d_D \leq x_3 \leq 0, \tag{10}$$

Where  $T_0 = \frac{k_B d_B T_u + k_B d_D T_l}{k_D d_B + k_B d_D}$ ,

$$x = d_B x^*_B, \quad v_B = \frac{\lambda_B}{d_B} v^*_B, \quad \theta_B = |T_0 - T_u| \theta^*_B, \tag{15}$$

**B. The Perturbation Equations**

Suppose that the equilibrium solution be perturbed by following linear perturbation quantities:

$$\begin{aligned} V_B &= 0 + \varepsilon v_B, & P_B &= P_B(x_3) + \varepsilon p_B, \\ T_B &= T_0 - (T_0 - T_u) \frac{x_3}{d_B} + \varepsilon \theta_B, \end{aligned} \tag{11}$$

$$\begin{aligned} V_D &= 0 + \varepsilon v_D, & P_D &= P_D(x_3) + \varepsilon p_D, \\ T_D &= T_0 - (T_l - T_0) \frac{x_3}{d_D} + \varepsilon \theta_D, \end{aligned}$$

then we may verify that the linearised version of equations (2) are

$$\begin{aligned} \frac{\rho_0}{\varphi_B} \frac{\partial v_B}{\partial t} &= -\nabla p_B - \frac{\mu}{K_B} v_B + \rho_0 \alpha g \theta_B, \\ \frac{\partial \theta_B}{\partial t} - v_B \frac{(T_u - T_0)}{d_B} &= k_B \nabla^2 \theta_B, \end{aligned} \tag{12}$$

and equations (3) are

$$\begin{aligned} \frac{\rho_0}{\varphi_D} \frac{\partial v_D}{\partial t} &= -\nabla p_D - \frac{\mu}{K_D} v_D + \rho_0 \alpha g \theta_D, \\ \frac{\partial \theta_D}{\partial t} - v_D \frac{(T_l - T_0)}{d_D} &= k_D \nabla^2 \theta_D, \end{aligned} \tag{13}$$

The boundary conditions (4)-(6) become respectively

$$\begin{aligned} w_B(d_B) &= 0, & \frac{\partial w_B}{\partial x_3}(d_B) &= 0, & \theta_B(d_B) &= 0, \\ \theta_B(0) &= \theta_D(0), & k_B \frac{\partial \theta_B}{\partial x_3}(0) &= k_D \frac{\partial \theta_D}{\partial x_3}(0), \\ w_B(0) &= w_D(0), & -p_B(0) + 2\mu \frac{\partial w_B}{\partial x_3}(0) &= -p_D(0), \\ w_D(-d_D) &= 0, & \frac{\partial w_D}{\partial x_3}(-d_D) &= 0, & \theta_D(-d_D) &= 0. \end{aligned} \tag{14}$$

**C. Non-Dimensionalisation**

We now non-dimensionalize the equations (12) and (13) by using the transformation

for the fluid layer, and using the transformation

$$x = d_D x^*_D, \quad v_D = \frac{\lambda_D}{d_D} v^*_D, \quad \theta_D = |T_l - T_0| \theta^*_D, \tag{16}$$

$$p_D = \frac{\mu \lambda_D}{K_D} p^*_D, \quad t = \frac{d_D^2}{\lambda_D} t^*_D,$$

Thus equations (12) can be written in the form

$$\begin{aligned} \frac{Da_B}{\varphi_B P_{rB}} \frac{\partial v_B}{\partial t_B} &= -\nabla p_B - v_B + Da_B \nabla^2 v_B + Rt_B \theta_B, \\ \frac{\partial \theta_B}{\partial t_B} + Fv_B &= \nabla^2 \theta_B, \end{aligned} \tag{17}$$

where  $P_{rB}, Da_B$  and  $Rt_B$  are non-dimensional numbers denote the viscous Prandtl number, Darcy number and thermal Rayleigh number of the porous layer  $L_1$  and given by

$$P_{rB} = \frac{\mu}{\rho_0 \lambda_B}, \quad Da = \frac{K_B}{d_B^2}, \quad Rt_B = \frac{\rho_0 g \alpha |T_0 - T_u| K_B d_B}{\mu \lambda_B}, \tag{18}$$

and the equations (13) can be written in the form

$$\begin{aligned} \frac{Da_D}{\varphi_D P_{rD}} \frac{\partial v_D}{\partial t_D} &= -\nabla p_D - v_D + Rt_D \theta_D, \\ \frac{\partial \theta_D}{\partial t_D} + Fv_D &= \nabla^2 \theta_D, \end{aligned} \tag{18}$$

where  $P_{rD}, Da_D$  and  $Rt_D$  are non-dimensional numbers denote viscous Prandtl number, Darcy number and thermal Rayleigh number of the porous medium layer  $L_2$  and given by:

$$P_{rD} = \frac{\mu}{\rho_0 \lambda_D}, \quad Da_D = \frac{K_D}{d_D^2}, \quad Rt_D = \frac{g \alpha |T_l - T_0| K_D d_D}{\mu \lambda_D},$$

and where

$$F = \frac{-(T_0 - T_u)}{|T_0 - T_u|} = \frac{-(T_l - T_0)}{|T_l - T_0|} = \begin{cases} -1, & \text{when heating from below,} \\ 1, & \text{when heating from above.} \end{cases}$$

condition on the interface plane (19)<sub>7</sub> by eliminate hydrostatic pressure term so taking tow-dimensional Laplacian of (19)<sub>7</sub> we obtain:

We will discuss the problem in case of heating from below, so we take  $F = -1$ . Using (15) and (16) in the boundary conditions (14) we obtain

$$\begin{aligned} w_B(1) = 0, \quad \frac{\partial w_B}{\partial x_3}(1) = 0, \quad \theta_B(1) = 0, \\ \gamma_T \theta_B(0) = \theta_D(0), \quad \frac{\partial \theta_B}{\partial x_3}(0) = \frac{\partial \theta_D}{\partial x_3}(0), \end{aligned} \tag{19}$$

$$w_B(0) = \gamma_T w_D(0), \quad \frac{1}{\gamma_T \hat{d}} Da_D \left[ \frac{1}{Da_B} p_B(0) - 2 \frac{\partial w_B}{\partial x_3}(0) \right] = p_D(0),$$

$$w_D(-1) = 0, \quad \frac{\partial w_D}{\partial x_3}(-1) = 0, \quad \theta_D(-1) = 0,$$

where  $\hat{d}, \varepsilon_r, \gamma_T$  and  $\hat{K}$  are given by

$$\hat{d} = \frac{d_B}{d_D}, \quad \varepsilon_r = \frac{k_B}{k_D}, \quad \gamma_T = \frac{|T_u - T_0|}{|T_0 - T_l|} = \frac{\hat{d}}{\varepsilon_r}, \quad \hat{K} = \frac{K_B}{K_D},$$

And  $P_{r_B} = \frac{1}{\varepsilon_r} P_{r_D}, \quad Da_B = \frac{\hat{K}}{\hat{d}} Da_D, \quad Rt_B = \frac{\hat{d}^4 Da_B}{\varepsilon_r^2 Da_D} Rt_D.$

**Note:** the  $(\bullet)$  superscript has been dropped from equations (17)-(19) for simplify.

*D. Linearisation of Equations*

We take the curl curl of the equations (17)<sub>1</sub> and (18)<sub>1</sub> to eliminate  $p_B$  and  $p_D$  respectively and considering the third component of the result equations and the equations (17)<sub>2</sub> and (18)<sub>2</sub>, we get

$$\frac{Da_B}{\phi_B P_{r_B}} \frac{\partial}{\partial t} \nabla^2 w_B = -\nabla^2 w_B + Da_B \nabla^4 w_f + Rt_B \nabla^2 \theta_B, \tag{20}$$

$$\frac{\partial \theta_B}{\partial t} - w_B = \nabla^2 \theta_B,$$

and

$$\frac{Da_D}{\phi_D P_{r_D}} \frac{\partial}{\partial t} \nabla^2 w_D = -\nabla^2 w_D + Rt_D \nabla^2 \theta_D, \tag{21}$$

$$\frac{\partial \theta_D}{\partial t} - w_D = \nabla^2 \theta_D.$$

where  $\nabla^2 = \nabla^2 - \frac{\partial^2}{\partial x_3^2}$  is tow-dimensional Laplacian operator

and  $\nabla^4 = (\nabla^2)^2$ . To simple the normal stress boundary

$$\frac{1}{\gamma_T \hat{d}^3} Da_D \left[ \frac{1}{Da_B} \nabla^2 p_B(0) - 2 \frac{\partial}{\partial x_3} \nabla^2 w_B(0) \right] = \nabla^2 p_m(0). \tag{22}$$

Since

$$\begin{aligned} \nabla \cdot v_B = 0 &\Rightarrow \frac{\partial u_B}{\partial x_1} + \frac{\partial v_B}{\partial x_2} = -\frac{\partial w_B}{\partial x_3}, \\ \nabla \cdot v_D = 0 &\Rightarrow \frac{\partial u_D}{\partial x_1} + \frac{\partial v_D}{\partial x_2} = -\frac{\partial w_D}{\partial x_3}. \end{aligned} \tag{23}$$

then we take the divergence of equations (17)<sub>1</sub> and (18)<sub>1</sub> we get respectively

$$\nabla^2 p_B = \frac{Da_B}{\phi_B P_{r_B}} \frac{\partial}{\partial t} \frac{\partial w_B}{\partial x_3} + \frac{\partial w_B}{\partial x_3} - Da_B \nabla^2 \frac{\partial w_B}{\partial x_3}, \tag{24}$$

$$\nabla^2 p_D = \frac{Da_D}{\phi_D P_{r_D}} \frac{\partial}{\partial t} \frac{\partial w_D}{\partial x_3} + \frac{\partial w_D}{\partial x_3}. \tag{25}$$

Substitute (24) and (25) in (22) we have

$$\begin{aligned} \frac{1}{\gamma_T \hat{d}^3} Da_D \frac{\partial}{\partial x_3} \left( \nabla^2 w_B(0) - \frac{1}{Da_B} w_B - \frac{1}{\phi_B P_{r_B}} \frac{\partial w_B}{\partial t}(0) \right) + \\ 2 \nabla^2 w_B(0) = - \left( \frac{Da_D}{\phi_D P_{r_D}} \frac{\partial}{\partial t} + 1 \right) \frac{\partial w_D}{\partial x_3}(0). \end{aligned} \tag{26}$$

Now we look for solution of the form

$$\Phi(x, t) = \Phi(x_3) \exp[i(n x_1 + m x_2) + \sigma t],$$

for the functions  $w_B, \theta_B, w_D$  and  $\theta_D$ . Thus the governing equation are:

$$\begin{aligned} \frac{Da_B}{\phi_B P_{r_B}} \sigma_B L_B w_B &= -L_B w_B + Da_B L_B^2 w_B - a_B^2 Rt_B \theta_B, \\ \sigma_B \theta_B &= w_B + L_B \theta_B, \\ -\frac{Da_D}{\phi_D P_{r_D}} \sigma_D L_D w_D &= L_D w_D + a_D^2 Rt_D \theta_D, \\ \sigma_D \theta_D &= w_D = L_D \theta_D, \end{aligned} \tag{27}$$

where  $a_B = \sqrt{n_B^2 + m_B^2}$  and  $a_D = \sqrt{n_D^2 + m_D^2}$  are non-dimensional wave numbers in the fluid layer and porous medium layer respectively,  $\sigma$  is the growth rate and

$$a_B = \hat{d}a_D, \quad \sigma_B = \frac{\hat{d}^2}{\varepsilon_T} \sigma_D, \quad D_D = \frac{\partial}{\partial x_3}, \quad x_3 \in [-1,0],$$

$$D_B = \frac{\partial}{\partial x_3}, \quad x_3 \in [0,1],$$

$$L_B = (D_B^2 - a_B^2), \quad \text{and} \quad L_D = (D_D^2 - a_D^2).$$

The final boundary conditions are:

$$w_B = 0, \quad D_B w_B = 0, \quad \theta_B = 0, \quad \text{on } x_3 = 1, \quad (28)$$

$$\left. \begin{aligned} w_B &= \gamma_T w_D, & \gamma_T \theta_B &= \theta_D, \\ D_B \theta_B &= D_D \theta_D, \\ \frac{1}{\gamma_T \hat{d}^3} D a_D \left( D_B^3 w_B - \frac{1}{D a_B} D_B w_B - \right. \\ & \left. 3 a_B^2 D_B w_B - \frac{\sigma_B}{\phi_B P_{rB}} D_B w_B \right) = \\ & \left. - \left( \frac{D a_D}{\phi_D P_{rD}} \sigma_D + 1 \right) D_D w_D, \right\} \text{on } x_3 = 0, \quad (29)$$

$$w_D = 0, \quad D_D w_D = 0, \quad \theta_D = 0, \quad \text{on } x_3 = -1. \quad (30)$$

### III. NUMERICAL SOLUTION

A Legendre polynomials is applied to solve the equations (27) with the relevant boundary conditions (28)-(30), and we map  $x_3 \in [0,1]$  and  $x_3 \in [-1,0]$  in to  $z \in [-1,1]$  by the transformations  $z = 2x_3 - 1$  and  $z = 2x_3 + 1$  respectively, and get

$$\frac{\partial}{\partial x_3} = 2 \frac{\partial}{\partial z}, \quad \text{thus} \quad D_B = D_D = 2 \frac{\partial}{\partial z} = D, \quad z \in [-1,1].$$

then, suppose that

$$y_r(z) = \sum_{k=0}^{M-1} \alpha_{kr} P_k(z), \quad 1 \leq r \leq 10 \quad z \in [-1,1],$$

let the variables  $y_r$  where  $1 \leq r \leq 10$  be defined by:

$$\begin{aligned} y_1 &= w_B, & y_2 &= D_B w_B, & y_3 &= D_B^2 w_B, & y_4 &= D_B^3 w_B, \\ y_5 &= \theta_B, & y_6 &= D_B \theta_B, \\ y_7 &= w_D, & y_8 &= D_D w_D, & y_9 &= \theta_D, & y_{10} &= D_D \theta_D. \end{aligned} \quad (31)$$

Then the equations (27) can be rewritten in a system of eighteen ordinary differential equations of first order as follows

$$\begin{aligned} D_B y_1 &= y_2, \\ D_B y_2 &= y_3, \end{aligned}$$

$$\begin{aligned} D_B y_3 &= y_4, \\ D_B y_4 &= - \left( \frac{a_B^2}{D a_B} + a_B^4 \right) y_1 + \left( 2 a_B^2 + \frac{1}{D a_B} \right) y_3 + \frac{a_B^2}{D a_B} R t_B y_5 + \\ & \frac{\sigma_B}{\phi_B P_{rB}} (y_3 - a_B^2 y_1), \end{aligned}$$

$$D_B y_5 = y_6,$$

$$D_B y_6 = -y_1 + a_B^2 y_5 + \sigma_B y_5,$$

$$D_D y_7 = y_8,$$

$$D_D y_8 = a_D^2 y_7 - a_D^2 R t_D y_9 + \sigma_D \frac{D a_D}{\phi_D P_{rD}} (a_D^2 y_7 - D y_8),$$

$$D_D y_9 = y_{10},$$

$$D_D y_{10} = -y_7 + a_D^2 y_9 + \sigma_D y_9,$$

and the boundary conditions are

$$y_1 = 0, \quad y_2 = 0, \quad y_5 = 0, \quad \text{on } z = 1,$$

$$\left. \begin{aligned} y_1(-1) - \gamma_T y_7(1) &= 0, & \gamma_T y_5(-1) - y_9(1) &= 0, \\ y_6(-1) - y_{10}(1) &= 0, \\ \frac{1}{\gamma_T \hat{d}^3} D a_D \left( y_4(-1) - \left( \frac{1}{D a_B} + 3 a_B^2 \right) y_2(-1) + \right. \\ & \left. y_8(1) \right) = \sigma \left( \frac{\hat{d}^2}{\varepsilon_T \phi_B P_{rB}} y_2(-1) - \frac{D a_D}{\phi_D P_{rD}} y_8(1) \right), \end{aligned} \right\} \text{on } z = 0$$

$$y_7 = 0, \quad y_8 = 0, \quad y_9 = 0, \quad \text{on } z = -1,$$

Since  $D_B = D_D = D$  and if we put  $\sigma_m = \sigma$  then  $\sigma_B = \frac{\hat{d}^2}{\varepsilon_T} \sigma$  so the eigenvalue problem can be reformulated in the form

$$\frac{dY}{dz} = AY + \sigma BY, \quad z \in [-1,1],$$

where  $A$  and  $B$  are real  $10 \times 10$  matrices.

### IV. RESULTS AND DISCUSSION

The eigen value problem (27) with boundary conditions (28)- (30) by using Legendre polynomials is transformed to a system of five ordinary differential equations of first order in the porous layer  $L_1$  and a system of five ordinary differential equations of first order in the porous layer  $L_2$  with ten boundary conditions. We will find the thermal Rayleigh numbers of the porous medium  $R t_D$  corresponding to the wave numbers  $a_D$  for different values of depth ratio  $\hat{d}$ , permeability ratio  $\hat{K}$  and thermal conductivity ratio  $\varepsilon_T$  as shown in the following Figs. 2-9. Therefore, we concluded that:

- The deeper the space between the two porous layers is the less value the thermal Rayleigh numbers will be, which leads to the instability of the fluid. This means that the less deep the Darcy, governed porous layer is the more the thermal convection, as shown in Fig. 2.
- The increases of the rate of permeability  $\hat{K}$  helps suppress the thermal convection which leads to the stability of the fluid. This case becomes clearer when the space between two porous layers decreases, as shown in Figs. 3-5.
- As thermal conductivity ratio  $\varepsilon_T$  increases, the thermal Rayleigh number increases. This means that when the porous layer governed by Brinkman's model is more thermal conductive than the porous layer governed by Darcy's model it helps stabilize the fluid. This case becomes more clear when the space between two porous layers decreases and the rate of permeability increases, as shown in Figs. 6-9.

Fig. 2 The relation between  $a_D$  and  $Rt_D$  for different value of  $\hat{d}$ ,  $Da_D = 4 \times 10^{-6}$ ,  $\varepsilon_T = 0.7$  and  $\hat{K} = 0.01$

Fig. 3 The relation between  $a_D$  and  $Rt_D$  for different value of  $\hat{K}$ ,  $\hat{d} = 0.14$ ,  $Da_D = 4 \times 10^{-6}$  and  $\varepsilon_T = 0.7$

Fig. 4 The relation between  $a_D$  and  $Rt_D$  for different value of  $\hat{K}$ ,  $\hat{d} = 0.09$ ,  $Da_D = 4 \times 10^{-6}$  and  $\varepsilon_T = 0.7$

Fig. 5 The relation between  $a_D$  and  $Rt_D$  for different value of  $\hat{K}$ ,  $\hat{d} = 0.08$ ,  $Da_D = 4 \times 10^{-6}$  and  $\varepsilon_T = 0.7$

Fig. 6 The relation between  $a_D$  and  $Rt_D$  for different value of  $\varepsilon_T$ ,  $\hat{K} = 0.01$ ,  $\hat{d} = 0.14$  and  $Da_D = 4 \times 10^{-6}$

Fig. 7 The relation between  $a_D$  and  $Rt_D$  for different value of  $\epsilon_T$ ,  $\hat{K} = 0.01$ ,  $\hat{d} = 0.2$  and  $Da_D = 4 \times 10^{-6}$

Fig. 8 The relation between  $a_D$  and  $Rt_D$  for different value of  $\epsilon_T$ ,  $\hat{K} = 0.001$ ,  $\hat{d} = 0.14$  and  $Da_D = 4 \times 10^{-6}$

Fig. 9 The relation between  $a_D$  and  $Rt_D$  for different value of  $\epsilon_T$ ,  $\hat{K} = 0.02$ ,  $\hat{d} = 0.14$  and  $Da_D = 4 \times 10^{-6}$ .
