# The Mutated Distance between Two Mixture Trees 

Wan Chian Li, Justie Su-Tzu Juan*, Yi-Chun Wang, and Shu-Chuan Chen

#### Abstract

The evolutionary tree is an important topic in bioinformation. In 2006, Chen and Lindsay proposed a new method to build the mixture tree from DNA sequences. Mixture tree is a new type evolutionary tree, and it has two additional information besides the information of ordinary evolutionary tree. One of the information is time parameter, and the other is the set of mutated sites. In 2008, Lin and Juan proposed an algorithm to compute the distance between two mixture trees. Their algorithm computes the distance with only considering the time parameter between two mixture trees. In this paper, we proposes a method to measure the similarity of two mixture trees with considering the set of mutated sites and develops two algorithm to compute the distance between two mixture trees. The time complexity of these two proposed algorithms are $O\left(n^{2} \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\}\right)$ and $O\left(n^{2}\right)$, respectively.

Keywords-evolutionary tree, mixture tree, mutated site, distance.

## I. Introduction

THE phylogenetic trees or evolutionary trees are described in the relationship of species. Using species information to build phylogenetic trees is a popular problem. The species information is including species external, species frame and DNA sequence, etc. There are many methods to build trees, like neighbor-joining [1], maximum likelihood [2], and so on. In this topic, to propose a method for building trees must do bootstrapping. Different trees could be built by a data set, even if using the same method [3]. Besides, the comparison of phylogenetic trees is necessary when we execute phylogenetic queries on databases of phylogenetic trees [4]. Thus, this is an important problem that how to measure distance between two trees for tree comparison. It is difficult to compare two trees. Unlike the comparison of two numbers or points in space [5], there does not have obvious or natural way to measure the distance between two trees. Many tree comparison metrics have been proposed before, including the partition metric [6], the quartet metric [7], the nearest neighborhood interchange metric [8], the metric from the nodal distance algorithm [9], etc. In 2006, Chen and Lindsay proposed a new method to build the mixture tree from DNA sequences [10]. Mixture tree is a type of evolutionary tree. Mixture tree has two information. One of the information is time parameter, and the other is the set of mutated sites. Fig. 1 shows a mixture tree.

In 2008, Lin and Juan gave a definition, called mixture distance, and the corresponding algorithm to compute distance between two mixture trees [11]. However, their algorithm only considers the time parameter for computing the distance

between two mixture trees. Moreover, the time complexity of this algorithm is $O(n \log n)$. In this paper, we give a new definition of distance, called mutated distance, between two mixture trees by considering the set of mutated sites. And we also give a corresponding algorithm to computes the mutated distance between two mixture trees. Then, we also give an improved algorithm, such that the time complexity of this algorithm is $O\left(n^{2}\right)$. We use the path difference metric [12] concept to define the distance and design our algorithm by using the concept of Lin and Juan's algorithm [11]. Hence, it is easy to combine our algorithm with Lin and Juan's algorithm [11].

Path difference metric [5] - It was mentioned by Penny and Hendy in 1985. Let $d_{i j}(T)$ denote the number of edges in the path which join two leaves that labeled by $i$ and $j$ in $T$, and let $d(T)$ be the associate vector obtained by fixed ordering of the $\operatorname{pairs}(i, j) . d_{p}\left(T_{1}, T_{2}\right)$ denotes the Euclidean distance between the two vector $d\left(T_{1}\right)$ and $d\left(T_{2}\right)$. That is, $d_{p}\left(T_{1}, T_{2}\right)$ is the square root of the sum of the squares of the difference $d_{i j}\left(T_{1}\right)-d_{i j}\left(T_{2}\right)$. The distance between two phylogenetic trees $T_{1}$ and $T_{2}$ is defined as $\operatorname{Distance}\left(T_{1}, T_{2}\right)=d_{p}\left(T_{1}, T_{2}\right)=\left\|d\left(T_{1}\right)-d\left(T_{2}\right)\right\|_{2}$. Williams and Clifford [13] defined a similar dissimilarity measure on trees, except using an $\mathrm{L}^{1}$-norm rather than $\mathrm{L}^{2}$-norm. That is, Distance $\left(T_{1}, T_{2}\right)=d_{p}\left(T_{1}, T_{2}\right)=$ $\left\|d\left(T_{1}\right)-d\left(T_{2}\right)\right\|_{1}$.

The mixture distance [11] - In 2008, Lin and Juan proposed mixture distance denoted by $d_{m}$, as the sum of the difference of $P_{T_{i}}(x, y)$ for any two leaves $x, y$. That is, the mixture distance between two mixture trees $T_{1}, T_{2}$ is defined as $d_{m}\left(T_{1}, T_{2}\right)=\Sigma_{x, y \in V^{\prime}}\left|P_{T_{1}}(x, y)-P_{T_{2}}(x, y)\right|$, where $V^{\prime}$ is the set of leaves of $T_{1}$ (equals to the set of leaves of $T_{2}$ ) and $P_{T_{i}}(x, y)$ denote the time parameter of the least

common ancestor of two leaves $x, y$ in tree $T_{i}$ for $i=1,2$. Their corresponding algorithm, called the mixture distance algorithm, only compares the least common ancestor of two leaves in two trees. For an internal node in $T_{1}$, the mixture distance algorithm finds all pairs of leaves which the least common ancestor is this internal node. Then, this algorithm finds the least common ancestors of those leaves in $T_{2}$, and calculates the distance. In order to implement this approach, similar to [12], they used two colors to color leaves of $T_{2}$ according to $T_{1}$.

Definition 1. [14] There are many topological spaces in which the topology is derived from a notion of distance. A metric for a set $X$ is a function $d$ on the cartesian product $X \times X$ to the non-negative reals such that for all points $x, y$ and $z$ of $X$,
(a) $d(x, y)=d(y, x)$,
(b) (triangle inequality) $d(x, y)+d(y, z) \geq d(x, z)$,
(c) $d(x, y)=0$ if $x=y$, and
(d) $x=y$ if $d(x, y)=0$.

The last one of these conditions is inessential for many purposes. A function $d$ which satisfies only (a), (b) and (c) is called a pseudo-metric.

In Section II, we define a new metric, the mutated distance, to measure the distance between two mixture trees, and we also show that this metric is a pseudo-metric. In Section III, a algorithm for the mutated distance is proposed. Section IV will proposes an improved algorithm for the mutated distance.

## II. The Metric: Mutated Distance

Throughout this paper, we only discuss the full binary tree. A fully resolved tree is a tree in which every node bifurcates [15], and it also is called a full binary tree. The full binary tree is a tree $T=(V, E)$ with $V$ nodes and $n$ leaves, and each node $v_{i}$ has either two children or no child. The node without child is called a leaf, which is associated with a species. Because we discuss mixture trees, every node $v_{i}$ will be associated with a set $M S_{T}\left(v_{i}\right)$, mutated sites set, that records the set of all sites of a species mutation occuring from its father. Fig. 2 shows the data tree of the mixture tree in Fig. 1.

Fig. 2. A data tree for the associated mixture tree $M_{1}$.

In a tree $T=(V, E)$, let $V^{\prime}(T)$ be the leaves vertex set of $T$. Let $L C A_{T}(x, y)$ be the least common ancestors of
$x, y \in V^{\prime}(T)$ in $T$. Let $V_{T}(x, y)$-path be the vertex set of $(x, L C A T(x, y))$-path-LCAT $(x, y)$ in $T$.

The notation $\triangle$ is symmetric difference of two sets. Let $\operatorname{LCA}_{T}(x, y)$ be the least common ancestors of $x, y \in V^{\prime}(T)$ in $T$. Let $V_{T_{i}}(x, y)$-path be the vertex set of $\left(x, \mathrm{LCA}_{T}(x, y)\right)$-path- $\mathrm{LCA}_{T}(x, y)$ in $T$. Let $V_{T_{i}}(x, y)$ path $=\left\{v_{1}=x, v_{2}, \ldots, v_{t}=\operatorname{LCA}_{T}(x, y)\right\}$, and $S_{T}(x, y)$ be the set of $\operatorname{MS}_{T}\left(v_{1}\right) \triangle \mathrm{MS}_{T}\left(v_{2}\right) \triangle \ldots \triangle \mathrm{MS}_{T}\left(v_{t}-1\right)$. Define $d^{\prime}\left(T_{1}, T_{2}\right)$ be the mutated distance between two mixture trees, $T_{1}$ and $T_{2}$, by $d^{\prime}\left(T_{1}, T_{2}\right)=$ $\sum_{x, y \in V^{\prime}}\left(\left|S_{T_{1}}(x, y) \triangle S_{T_{2}}(x, y)\right|+\left|S_{T_{1}}(y, x) \Delta S_{T_{2}}(y, x)\right|\right)$ where $V^{\prime}=V^{\prime}\left(T_{1}\right)=V^{\prime}\left(T_{2}\right)$.

From following Theorems 1, 2, 3 and Example 1, we prove that our metric is a pseudo-metric.

Theorem 1. The mutated distance $d^{\prime}$ satisfies $d^{\prime}(A, B)=$ $d^{\prime}(B, A)$ for any two trees $A, B$.
Proof. Because $\left|S_{A}(x, y) \triangle S_{B}(x, y)\right|=\left|S_{B}(x, y) \triangle S_{A}(x, y)\right|$ and $\left|S_{A}(y, x) \triangle S_{B}(y, x)\right|=\left|S_{B}(y, x) \triangle S_{A}(y, x)\right|$, for any two leaves $x, y . d^{\prime}(A, B)=\sum_{x, y \in V^{\prime}} \mid S_{A}(x, y) \triangle$ $S_{B}(x, y)\left|+\left|S_{A}(y, x) \triangle S_{B}(y, x)\right|=\sum_{x, y \in V^{\prime}}\right| S_{B}(x, y) \triangle$ $S_{A}(x, y)\left|+\left|S_{B}(y, x) \triangle S_{A}(y, x)\right|=d^{\prime}(B, A)\right.$

Theorem 2. The mutated distance $d^{\prime}$ satisfies the triangle inequality.

Proof. Let $T_{1}, T_{2}$ and $T_{3}$ are three mixture trees with the same set of leaves $V^{\prime}$. By the definition,
$d^{\prime}\left(T_{1}, T_{2}\right)=\sum_{x, y \in V^{\prime}}\left(\left|S_{T_{1}}(x, y) \triangle S_{T_{2}}(x, y)\right|+\mid S_{T_{1}}(y, x)\right.$ $\left.\triangle S_{T_{2}}(y, x) \mid\right), d^{\prime}\left(T_{2}, T_{3}\right)=\sum_{x, y \in V^{\prime}}\left|S_{T_{2}}(x, y) \triangle S_{T_{3}}(x, y)\right|$ $+\left|S_{T_{2}}(y, x) \quad \triangle \quad S_{T_{3}}(y, x)\right| \quad$ and $d^{\prime}\left(T_{3}, T_{1}\right)=$ $\sum_{x, y \in V^{\prime}}\left|S_{T_{3}}(x, y) \triangle S_{T_{1}}(x, y)\right|+\left|S_{T_{3}}(y, x) \Delta S_{T_{1}}(y, x)\right|$
Our goal is to prove $d^{\prime}\left(T_{1}, T_{2}\right)+d^{\prime}\left(T_{2}, T_{3}\right) \geq d^{\prime}\left(T_{3}, T_{1}\right)$. Since the distance is the sum of two terms of symmetric difference operations. So, if we prove that one of these two terms satisfies triangle inequality, the whole inequality will hold
Let $S_{1}(x, y)=\left|S_{T_{1}}(x, y) \triangle S_{T_{2}}(x, y)\right|+\mid S_{T_{2}}(x, y) \triangle$ $S_{T_{3}}(x, y)\left|-\left|S_{T_{3}}(x, y) \triangle S_{T_{1}}(x, y)\right| \geq 0, S_{2}(x, y)=\right.$ $\left|S_{T_{1}}(y, x) \triangle S_{T_{2}}(y, x)\right|+\left|S_{T_{2}}(y, x) \triangle S_{T_{3}}(y, x)\right|-\mid S_{T_{3}}(y, x) \triangle$ $S_{T_{1}}(y, x) \mid \geq 0$ for any two leaves $x$ and $y$ in $V^{\prime}$. We have $S_{1}(x, y)=\left|S_{T_{1}}(x, y) \triangle S_{T_{2}}(x, y)\right|+\left|S_{T_{2}}(x, y) \triangle S_{T_{3}}(x, y)\right|-$ $\left|S_{T_{3}}(x, y) \triangle S_{T_{1}}(x, y)\right|=\left|S_{T_{1}}(x, y) \cup S_{T_{2}}(x, y)\right|-\mid S_{T_{1}}(x, y) \cap$ $S_{T_{2}}(x, y)\left|+\left|S_{T_{2}}(x, y) \cup S_{T_{3}}(x, y)\right|-\left|S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right|-\right.$ $\left|S_{T_{3}}(x, y) \cup S_{T_{1}}(x, y)\right|+\left|S_{T_{3}}(x, y) \cap S_{T_{1}}(x, y)\right|$
Since $\left|S_{T_{i}}(x, y) \cup S_{T_{j}}(x, y)\right|=\left|S_{T_{i}}(x, y)\right|+$ $\left|S_{T_{j}}(x, y)\right|-\left|S_{T_{i}}(x, y) \cap S_{T_{j}}(x, y)\right|, \quad S_{1}(x, y)=$ $\left\{\left|S_{T_{1}}(x, y)\right|+\left|S_{T_{2}}(x, y)\right|+\left|S_{T_{2}}(x, y)\right|+\left|S_{T_{3}}(x, y)\right|-\right.$ $2\left|S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right|-2\left|S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right|-$ $\left.\left|S_{T_{1}}(x, y)\right|-\left|S_{T_{2}}(x, y)\right|+2\left|S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right|\right\}=$ $\left\{2\left|S_{T_{2}}(x, y)\right|-2\left|S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right|-2 \mid S_{T_{2}}(x, y) \cap\right.$ $\left.S_{T_{3}}(x, y)|+2| S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y) \mid\right\}=2\left\{\left|S_{T_{2}}(x, y)\right|-\right.$ $\left|S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right|-\left|S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right|+\mid S_{T_{1}}(x, y) \cap$ $\left.S_{T_{3}}(x, y) \mid\right\}=2\left\{\left|S_{T_{2}}(x, y) \cup\left(S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|+\right.$ $\left|S_{T_{2}}(x, y) \cap\left(S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|-\mid\left(S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right) \cup$ $\left(S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right)|-|\left(S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right) \cap\left(S_{T_{2}}(x, y) \cap\right.$ $\left.\left.S_{T_{3}}(x, y)\right) \mid\right\}=2\left\{\left|S_{T_{2}}(x, y) \cup\left(S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|+\right.$
$\left|S_{T_{2}}(x, y) \cap S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right|-\mid\left(S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right) \cup$ $\left(S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right)\left|-\left|S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right|\right\}=$ $2\left\{\left|S_{T_{2}}(x, y) \cup\left(S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|-\mid\left(S_{T_{1}}(x, y) \cap\right.\right.$ $\left.\left.S_{T_{2}}(x, y)\right) \cup\left(S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right) \mid\right\}$.
Since $\left|S_{T_{2}}(x, y) \cup\left(S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right)\right| \geq\left|S_{T_{2}}(x, y)\right| \geq$ $\left|S_{T_{2}}(x, y) \cap\left(S_{T_{2}}(x, y) \cup S_{T_{3}}(x, y)\right)\right|$, we have $S_{1}(x, y)=2\left\{\left|S_{T_{2}}(x, y) \cup\left(S_{T_{1}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|-\right.$ $\left.\left|\left(S_{T_{1}}(x, y) \cap S_{T_{2}}(x, y)\right) \cup\left(S_{T_{2}}(x, y) \cap S_{T_{3}}(x, y)\right)\right|\right\} \geq 0$. In the same way, we can also prove that $S_{2} \geq 0$. Hence, adding these two terms for any leaves $x$ and $y$, we have $d^{\prime}\left(T_{1}, T_{2}\right)+d^{\prime}\left(T_{2}, T_{3}\right)-d^{\prime}\left(T_{3}, T_{1}\right)=$ $\sum_{x, y \in V^{\prime}}\left\{S_{1}(x, y)+S_{2}(x, y)\right\} \geq 0$.

Theorem 3. If tree $A$ is equal to tree $B$, the mutated distance $d^{\prime}(A, B)$ is zero.
Proof. If tree $A$ is equal to tree $B$, then $S_{A}(x, y)=$ $S_{B}(x, y)$ and $S_{A}(y, x)=S_{B}(y, x)$ for any two leaves $x$, $y$. Hence, $\left|S_{A}(x, y) \triangle S_{B}(x, y)\right|=0$ and $\mid S_{A}(y, x) \triangle$ $S_{B}(y, x) \mid=0$ for any two leaves $x, y$. That implies $\sum_{0 .}{ }_{x, y \in V^{\prime}}\left|S_{A}(x, y) \triangle S_{B}(x, y)\right|+\left|S_{A}(y, x) \triangle S_{B}(y, x)\right|=$
Example 1 shows that the mutated distance does not satisfy (d) $x=y$ if $d(x, y)=0$.

Example 1. There exist two mixture trees $A$ and $B$ in Fig. 3, such that the mutated distance of $A$ and $B, d^{\prime}(A, B)$, is zero, but tree $A$ dose not equal to tree $B$.

Fig. 3. $T_{1}$ and $T_{2}$ of a counterexample.

## III. The Algorithm for Mutated Distance

Firstly, we design an algorithm for mutated distance in Section III-A. Then, we give an example in Section III-B. Section III-C is analysis of this algorithm.

## A. The Algorithm

For finding the mutated distance $d^{\prime}$ of any two mixture trees, $T_{1}$ and $T_{2}$, we need find mutated site set data of a path $S_{T}(x, y)$ for $T=T_{1}$ and $T_{2}$ at first. In 2008, Lin and Juan proposed an algorithm to compute the distance of time parameter between two mixture trees [11]. Their algorithm use color information to find all the least common ancestors of any two leaves in each of two trees. That will reduce the complexity for finding for any two leaves $x$ and $y$ in $V^{\prime}=V^{\prime}\left(T_{1}\right)=V^{\prime}\left(T_{2}\right)$. We will use this idea, too.

Before introducing the algorithm, we have to understand some notations which are used in the algorithm.

- $\boldsymbol{T}_{\mathbf{1}} \cdot \boldsymbol{u}_{\boldsymbol{j}}$ denotes a node $u_{j}$ in $T_{1}$, where $j$ is in the order of BFS, $\boldsymbol{T}_{\mathbf{2}} . \boldsymbol{v}_{\boldsymbol{j}}$ denotes a node $v_{j}$ in $T_{2}$, where $j$ is in the order of BFS. Note that $T_{1} \cdot u_{i}=T_{2} \cdot v_{j}$ for some $j$ for any leaf $u_{i}$ of $T_{1}$ such that $T_{1} \cdot u_{i}\left(=T_{2} \cdot v_{j}\right)$ has the same sequence name with $v_{j}$ in $T_{2}$.
- color $\_i$ of $v_{i}$ denotes the color information of the subtree that rooted by $v_{i}$ in $T_{2}$. The color_ $i$ contains two integer: color_i.Red is the amount of leaves that are colored by red, and color_i.Green is the amount of leaves that are colored by green. For example, $A, B, C$ is three nodes in a tree. Let $B, C$ be two children of $A$, then color_ $i(A)=$ color_ $i(B)+$ color_ $i(C)$. That means, these two values color $\_i(A)$. Red $=$ color $\_i(B)$. Red + color $\_i(C) . R e d ;$ color $\_i(A) \cdot G r e e n=$ color $\_i(B) \cdot G r e e n+$ color_ $i(C)$. Green.
- sLeafTable $\boldsymbol{i}_{\boldsymbol{i}}$ is the leaves data of $T_{i}$ for $i=1,2$. The data include sequence name, BFS number and color information. The size of this table is $n \times 3$, where a row represents one leaf. The sequence name represents the sequence title of this leaf. The BFS number is the order of this leaf in the order of BFS. The color information is the color of this leaf, which will be green, red or null.
- d. $\boldsymbol{v}_{\boldsymbol{k}}$.Red (d.v. $\boldsymbol{v}_{\boldsymbol{k}}$ Green) of $T_{2} \cdot v_{k}$ for $T_{1} \cdot v_{j}$ and $T_{2} \cdot v_{j}$ denotes the sum of symmetric difference between $S_{T_{1}}\left(v_{j}, v_{i}\right)$ and $S_{T_{2}}\left(v_{j}, v_{k}\right)$ for $v_{k}$ in $\left(v_{1}, v_{j}\right)$-path of $T_{2}$ for any leaf $v_{j}$ when we fix $i$. And when we fix $v_{i}$, if the color of $v_{j}$ is red (green, respectively), this value will be stored in d.vk.red (d.vk.green, respectively). After computing all leaves $v_{j}, d . v_{k}$.Red (d. $v_{k}$.Green, respectively) is the sum of $S_{T_{2}}\left(v_{j}, v_{k}\right) \triangle S_{T_{1}}\left(v_{j}, v_{i}\right)$ for all leave $v_{j}$ in the subtree that rooted by $v_{k}$ which colored by red (green, respectively).
- $\boldsymbol{D}$ is the record of the mutated distance of $T_{1}$ and $T_{2}$.
- $\boldsymbol{S}_{\boldsymbol{T}_{2}}\left(\boldsymbol{v}_{j}\right)$ is a temporary for calculating $S_{T_{2}}\left(v_{j}, v_{k}\right)$ for any $v_{k}$ in $T_{2}$.
- $\boldsymbol{T}_{\boldsymbol{i}} \cdot \boldsymbol{v}_{\boldsymbol{j}} \cdot \boldsymbol{l}$ denotes the left child of $T_{i} \cdot v_{j}, \boldsymbol{T}_{\boldsymbol{i}} \cdot \boldsymbol{v}_{\boldsymbol{j}} \cdot \boldsymbol{l} \cdot \boldsymbol{r}$ denotes the right child of $T_{i} \cdot v_{j}$.
The algorithm of mutated distance is presented as follows.
Input: Two trees $T_{1}$ and $T_{2}$ with the same $n$ leaves.
Output: The mutated distance between $T_{1}$ and $T_{2}$.
- Step 1 Traversal $T_{1}$ and $T_{2}$, and give all nodes an order by BFS, respectively.
- Step 2 Find sLeafTable $e_{1}$ and sLeafTable $_{2}$, and sort $s^{\text {LeafTable }}{ }_{1}$ and sLeaf Table $e_{2}$ by sequence name.
- Step 3 For each internal node $u_{i}$ in $T_{1}$ do Step 4 to Step 13.
- Step 4 For the subtree which rooted by $T_{1} \cdot u_{i}$, color all leaves of its left subtree by red, and color all leaves of its right subtree by green. And color all leaves in $T_{2}$ by the same color this leaf be colored in $T_{1}$.
- Step 5 For each be colored leaf $v_{j}$ in $T_{2}$ do Step 6 to Step 12.
- Step 6 Use sLeafTable to find leaf $T_{1} \cdot v_{k}$ with the
same sequence name of $T_{2} \cdot v_{j}$, and find $S_{T_{1}}\left(v_{k}, u_{i}\right)$.
- Step 7 For any node $v_{l}$ in $\left(T_{2} \cdot v_{j}\right.$, root of $\left.T_{2}\right)$-path do Step 8 to Step 12.
- Step $8 S_{T_{2}}\left(v_{j}\right)$ is the symmetric difference of $S_{T_{2}}\left(v_{j}\right)$ and $\operatorname{MS}\left(T_{2} \cdot v_{l}\right)$.
- Step 9 If $T_{2} \cdot v_{j}$ is red to do Step 10.
- Step 10 Compute $d . v_{l}$.Red and color_i.Red $\left(T_{2} \cdot v_{l}\right)$, $d . v_{l}$.Red add the number of element of the symmetric difference of $S_{T_{1}}\left(v_{k}, u_{i}\right)$ and $S_{T_{2}}\left(v_{j}\right)$. And color_i.Red $\left(T_{2}\right.$. $\left.v_{l}\right)$ add 1.
- Step 11 If $T_{2} \cdot v_{j}$ is green to do Step 12.
- Step 12 Compute d.vl.Green and color_i.Green $\left(T_{2} \cdot v_{l}\right)$, d. $v_{l}$. Green add the number of element of the symmetric difference of $S_{T_{1}}\left(v_{k}, u_{i}\right)$ and $S_{T_{2}}\left(v_{j}\right)$. And color_i.Green $\left(T_{2} \cdot v_{l}\right)$ add 1.
- Step 13 For any internal node $v_{j}$ in $T_{2}$, compute mutated distance $D . D$ add the sum of color_i.Green $\left(v_{j} . l\right)$ multiplied by $d .\left(v_{j} \cdot r\right)$.Red, color_i.Red $\left(v_{j} \cdot r\right)$ multiplied by $d .\left(v_{j} . l\right) . G r e e n$, color_i.Green $\left(v_{j} . r\right)$ multiplied by $d .\left(v_{j} . l\right)$. Red and color_i.Red $\left(v_{j} . l\right)$ multiplied by d. $\left(v_{j} . r\right) . G r e e n$.

## B. An Example of the Algorithm

In Fig. 4 and Fig. 5, there are two trees $T_{1}$ and $T_{2}$, and the mutated site set of each node. First give $T_{1}$ and $T_{2}$ the BFS numbers $u_{1}, u_{2},, u_{13}$ and $v_{1}, v_{2},, v_{13}$. The sLeafTable ${ }_{1}$ is the leaf table of $T_{1}$ in Fig. 4. The sLeafTable $e_{2}$ is the leaf table of $T_{2}$ in Fig. 5. Table I shows the sLeafTable ${ }_{1}$ and sLeafTable ${ }_{2}$ sorted by sequence name. This algorithm uses the sLeafTable to find two leaves, which two leaves have the same sequence name of $T_{1}$ and $T_{2}$. Then, this algorithm uses the color to compute the mutated distance between $T_{1}$ and $T_{2}$. When we fix $u_{1}$ as the subroot which be computing currently in $T_{1}$, see Fig. 4. The leaves of the left subtree of $u_{1}$ are $\{A, B, C, F\}$ that are colored by red, and the leaves of the right subtree of $u_{1}$ are $\{D, E, G\}$ that are colored by green. The leaves in $T_{2}$ are colored by the same color. Table II shows after computing all leaves of $T_{2}$, the values of $d . v_{k}$.Red and $d . v_{k}$.Green, when the algorithm color all leaves of the left subtree of the subtree, which rooted by $T_{1} \cdot u_{1}$, by red; and color all leaves of its right subtree by green. Table III shows color_i values in the algorithm. We use these two tables to compute the mutated distance between two mixture trees. The mutated distance of $(A, E)$ path, $(B, E)$-path and $(C, E)$-path $=4 \times 3+12 \times 1=24$ were computed in $T_{2} \cdot v_{4}$. The mutated distance of $(D, F)$ path $=4 \times 1+4 \times 1=8$ was computed in $T_{2} \cdot v_{3}$. The mutated distance of $(A, G)$-path, $(B, G)$-path and $(C, G)$-path $=3 \times 3+9 \times 1=18$ were computed in $T_{2} \cdot v_{2}$. The mutated distances of $(A, D)$-path, $(B, D)$-path, $(C, D)$-path, $(F, G)$ path and $(F, E)$-path $=4 \times 3+12 \times 1+4 \times 2+8 \times 1=40$ were computed in $T_{2} \cdot v_{1}$. When the subtree which rooted by $T_{1} \cdot u_{1}$ round finish to compute mutated distance, the mutated distance $=24+8+18+40=90$.

Next round the algorithm will fix the node $u_{2}$, and consider the subtree which rooted by $T_{1} \cdot u_{2}$. Then, it will color all leaves

Fig. 4. $\quad T_{1}$ colored according to $u_{1}$ of $T_{1}$.

Fig. 5. $\quad T_{2}$ colored according to $u_{1}$ of $T_{1}$.
of its left subtree by red, and color all leaves of its right subtree by green, and compute mutated distance until each internal node of $T_{1}$ has been fixed. The mutated distance between two mixture trees will be computed. The mutated distance between $T_{1}$ and $T_{2}$ is 146 . Table IV shows the complete data when computing the mutated distance between $T_{1}$ and $T_{2}$.

## C. Analysis

The time complexity of BFS order is $O(n)$ in this algorithm. The time complexity while finds $s L a f t \operatorname{Table}_{i}$ is $O(n)$. The time complexity of thise algorithm while sorts $s$ LaftTable $_{i}$ is $O(n \log n)$. For each internal node of $T_{1}$ we compute color $_{-} i$, d. $v_{k}$.Red, d. $v_{k}$.Green and $D$ between two mixture trees of each node of $T_{2}$ in time $O\left(n \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\} \times s\right)$, where $s$ means the sequence length of the DNA sequence of species. The total time complexity is $O\left(n^{2} \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\} \times\right.$ $s)$. Since the sequence length $s$ is a constant value, the total time complexity is $O\left(n^{2} \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\}\right)$. When $T_{1}$ and $T_{2}$ are complete binary trees, the height of a tree is $\log$ n . Hence, the time complexity of our algorithm is $O\left(n^{2} \log n\right)$ for complete binary trees.

## IV. The Improved Algorithm for Mutated Distance

Firstly, we design an improved algorithm for mutated distance in Section IV-A. Then, we give an example in Section IV-B. Section IV-C is analysis of this algorithm.

## A. The Improved Algorithm

This algorithm improves the time complexity of modified algorithm, it transforms the data MS to TMS. The TMS of vertex represents the difference sites between the root of $T_{1}$ and this vertex. This algorithm uses TMS and color_ $i$ of vertex to compute the mutated distance between two mixture trees.

Before introducing the algorithm, we have to understand some notations which are used in the algorithm.

- $\boldsymbol{T}_{\mathbf{1}} \cdot \boldsymbol{u}_{\boldsymbol{j}}$ denotes a node $u_{j}$ in $T_{1}$, where $j$ is in the order of BFS, $\boldsymbol{T}_{\mathbf{2}} \cdot \boldsymbol{v}_{j}$ denotes a node $v_{j}$ in $T_{2}$, where $j$ is in the order of BFS. Note that $T_{1} \cdot u_{i}=T_{2} \cdot v_{j}$ for some $j$ for any leaf $u_{i}$ of $T_{1}$ such that $T_{1} \cdot u_{i}\left(=T_{2} \cdot v_{j}\right)$ has the same sequence name with $v_{j}$ in $T_{2}$.
- color_i of $v_{i}$ denotes the color information of the subtree that rooted by $v_{i}$ in $T_{2}$. The color_ $i$ contains two integer: color_i.Red is the amount of leaves that are colored by red, and color_i.Green is the amount of leaves that are colored by green. For example, $A, B, C$ is three nodes in a tree. Let $B, C$ be two children of $A$, then color_ $i(A)=$ color $\_i(B)+$ color_ $i(C)$. That means, these two values color_ $i(A)$. Red $=$ color_i(B).Red + color_i(C).Red; color_ $i(A) \cdot G r e e n=$ color $\_i(B) \cdot G r e e n+$ color $\_i(C) \cdot G r e e n$.
- sLeafTable $\boldsymbol{i}_{\boldsymbol{i}}$ is the leaves data of $T_{i}$ for $i=1,2$. The data include sequence name, BFS number, color information. The size of this table is $n \times 3$, where a row represents one leaf. And each row includes three items: the sequence name represents the sequence title of this leaf, the BFS number is the order of this leaf in the order of BFS, the color information is the color of this leaf, which will be green, red or null.
- $\boldsymbol{D}$ is the record of the mutated distance of $T_{1}$ and $T_{2}$.
- $\boldsymbol{S}_{\boldsymbol{T}_{2}}\left(\boldsymbol{v}_{\boldsymbol{j}}\right)$ is a temporary for calculating $S_{T_{2}}\left(v_{j}, v_{k}\right)$ for any $v_{k}$ in $T_{2}$.
- $\boldsymbol{T}_{i} \cdot \boldsymbol{v}_{\boldsymbol{j}} \cdot \boldsymbol{l}$ denotes the left child of $T_{i} \cdot v_{j}, \boldsymbol{T}_{\boldsymbol{i}} \cdot \boldsymbol{v}_{\boldsymbol{j}} \cdot \boldsymbol{r}$ denotes the right child of $T_{i} \cdot v_{j}$.
- Path_number of $v_{i}$ in $T_{2}$ denotes an integer that is the inner product of color information of the two children of the subtree that rooted by $v_{i}$. For example, let $B, C$ be two children of $A$, then the path number of $A$ is equal to color_ $i(B)$.Red $\times$ color $\_i(C)$.Green + color_i(B).Green $\times$ color_ $i(C)$.Red.
- TMS of $v_{i}$ denotes a set, which represents the difference mutated sites between root of $T_{1}$ and $v_{i}$. Moreover, this set reveals the distance between root of $T_{1}$ and $v_{i}$.

The improved algorithm of mutated distance is presented as follows.

Input: Two trees $T_{1}$ and $T_{2}$ with the same $n$ leaves.
Output: The mutated distance between $T_{1}$ and $T_{2}$.

- Step 1 Traversal $T_{1}$ and $T_{2}$, and give all nodes an order by BFS, seperatedly.
- Step 2 Find $s L e a f T a b l e e_{1}$ and sLeafTable $e_{2}$, and sort sLeafTable $e_{1}$ and sLeaf Table $e_{2}$ by sequence name.
- Step 3 Transform $T_{1}$, transformed set of mutated sites TMS of root in $T_{1}$ is null. For other node $u_{i}$ of $T_{1}$, compute TMS of node from $u_{2}$ to $u_{2 n-1}$; TMS of $u_{i}$ is the symmetric difference between TMS of the father of $u_{i}$ and $\operatorname{MS}\left(u_{i}\right)$.
- Step 4 Transform $T_{2}$, the $\operatorname{TMS}\left(v_{j}\right)$ of leaves in $T_{2}$ is the same with the $\operatorname{TMS}\left(u_{i}\right)$ of $T_{1}$ where $v_{j}$ and $u_{i}$ has the same sequence name. For any internal node $v_{j}$ of $T_{2}$, compute $\operatorname{TMS}\left(v_{j}\right)$ from leaf to root, TMS of $v_{j}$ is the symmetric difference between $\operatorname{TMS}\left(v_{j} . l\right)$ and $\operatorname{MS}\left(v_{j}\right)$ $\left(=\operatorname{TMS}\left(v_{j} . r\right)\right.$ and $\left.\operatorname{MS}\left(v_{j}\right)\right)$.
- Step 5 For each internal node $u_{i}$ in $T_{1}$, do Step 6

to Step 8.

- Step 6 For the subtree which rooted by $T_{1} . u_{i}$, color all leaves of its left subtree by red, and color all leaves of its right subtree by green. And color all leaves in $T_{2}$ by the same color this leaf be colored in $T_{1}$.
- Step 7 For each internal node $v_{j}$ in $T_{2}$ do Step 8
- Step 8 Compute color_i.Red $\left(v_{j}\right)$, color_i.Green $\left(v_{j}\right)$, Path-number and mutated distance $D$ from $v_{2 n-1}$ to $v_{1} ;$ color $\_i . \operatorname{Red}\left(v_{j}\right)$ is the sum of color_i.Red $\left(v_{j} . l\right)$ and color_i.Red $\left(v_{j} . r\right)$; color_i.Green $\left(v_{j}\right)$ is the sum of color_i.Green $\left(v_{j} . l\right)$ and color_i.Green $\left(v_{j} . r\right)$; Pathnumber is the sum of color_i.Green $\left(v_{j} . l\right)$ multiplied by color_i.Red $\left(v_{j} . r\right)$ and color_i.Green $\left(v_{j} . r\right)$ multiplied by color_i.Red $\left(v_{j} . l\right) ; D$ is Path-number multiplied by two times of the number of element of the symmetric difference between $\operatorname{TMS}\left(u_{i}\right)$ and $\operatorname{TMS}\left(v_{j}\right)$.

## B. An Example of the Improved Algorithm

We use the same example as previous section in Fig. 4 and Fig. 5 to present how does this algorithm work. There are two trees $T_{1}$ and $T_{2}$, and the mutated site set of each node. First transform Fig. 4 to Fig. 6 and transform Fig. 5 to Fig. 7. Then give $T_{1}$ and $T_{2}$ the BFS numbers $u_{1}, u_{2},, u_{13}$ and $v_{1}, v_{2},, v_{13}$. The sLeafTable ${ }_{1}$ is the leaf table of $T_{1}$ in Fig. 6. The sLeafTable $e_{2}$ is the leaf table of $T_{2}$ in Fig. 7. Table I shows the sLeafTable ${ }_{1}$ and sLeafTable $e_{2}$ sorted by sequence name. This algorithm uas the sLeafTable to find two leaves, which two leaves have the same sequence name of $T_{1}$ and $T_{2}$. Then this algorithm using the color to compute the mutated distance between $T_{1}$ and $T_{2}$. When we fix $u_{1}$ as the subroot which be computing currently in $T_{1}$, see Fig, 6. The leaves of the left subtree of $u_{1}$ are $\{A, B, C, F\}$ that are colored by red, and the leaves of the right subtree of $u_{1}$ are $\{D, E, G\}$ that are colored by green. The leaves in $T_{2}$ are colored by the same color. Table III shows color_ $i$ values in the algorithm. We use these table to compute the mutated distance between two mixture trees. The mutated distance of $(A, E)$-path, $(B, E)$-path and
$(C, E)$-path $=(0 \times 0+3 \times 1) \times 2 \times(|\{ \} \triangle\{9,16,12,15\}|)=$ $3 \times 2 \times 4=24$ were computed in $T_{2} \cdot v_{4}$. The mutated distance of $(D, F)$-path $=(1 \times 1+0 \times 0) \times 2 \times(\mid\{ \} \triangle$ $\{9,16,3,4\} \mid)=1 \times 2 \times 4=8$ was computed in $T_{2} . v_{3}$. The mutated distance of $(A, G)$-path, $(B, G)$-path and $(C, G)$-path $=(1 \times 0+3 \times 1) \times 2 \times(|\{ \} \triangle\{9,16,2\}|)=3 \times 2 \times 3=18$ were computed in $T_{2} . v_{2}$. The mutated distances of $(A, D)$ path, $(B, D)$-path, $(C, D)$-path, $(F, G)$-path and $(F, E)$-path $=(2 \times 1+3 \times 1) \times 2 \times(|\{ \} \triangle\{9,16,3,4\}|)=5 \times 2 \times 4=40$ were computed in $T_{2} \cdot v_{1}$. When finish the round of computing the mutated distance of the subtree which rooted by $T_{1} \cdot u_{1}$, the mutated distance $=24+8+18+40=90$.

Fig. 6. The transform $T_{1}$ colored according to $u_{1}$ of $T_{1}$.

Fig. 7. The transform $T_{2}$ colored according to $u_{1}$ of $T_{1}$.

Next round the algorithm will fix the node $u_{2}$, and consider the subtree which rooted by $T_{1} \cdot u_{2}$. Then, it will color all leaves of its left subtree by red, and color all leaves of its right subtree by green, and compute mutated distance until each internal node of $T_{1}$ has been fixed. The mutated distance between two mixture trees will be computed. The mutated distance between $T_{1}$ and $T_{2}$ is 146 . Table V shows the complete data when computing the mutated distance between $T_{1}$ and $T_{2}$.

## C. Analysis

The time complexity of BFS order is $O(n)$ in this algorithm. The time complexity of this algorithm which finds sLaftTable $_{i}$ is $O(n)$. The time complexity of this algorithm while sorts $s L a f t T a b l e e_{i}$ is $O(n \log n)$. The time complexity of this algorithm while transforms $T_{1}$ and $T_{2}$ is in time $O(n)$. For each internal node of $T_{1}$, we compute color_i and $D$ between two mixture trees of each node of $T_{2}$ in
time $O\left(n \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\} \times s\right)$, where $s$ means the sequence length of the DNA sequence of species. The total time complexity is $O\left(n^{2} \times s\right)$. Since the sequence length $s$ is a constant value, the total time complexity is $O\left(n^{2}\right)$. When $T_{1}$ and $T_{2}$ are complete binary trees, the height of a tree is $\log n$. Hence, the time complexity of our algorithm is $O(n \log n)$ for complete binary trees.

## V. Conclusion

In this work, we define a metric, the mutated distance, and propose two algorithms to compute the distance with considering the set of mutated sites between two mixture trees. Considering our algorithms and Lin and Juan's algorithms [16], these algorithms all calculate the distance between two mixture trees. In [16], Lin and Juan also proposed two algorithms, and these two algorithms focus on the time paremeter of mixture trees. Table VI shows the time complexity of these two algorithms and our two algorithms.

Hence, the two information of mixture trees are considered by our algorithms and Lin and Juans algorithms [16]. One can get a compound-distance $D_{c}$ for two mixture trees $T_{1}$ and $T_{2}$ by our mutated distance $d^{\prime}$ and mixture distance (or mixture-matching distance) $d_{m}$ [16]. That means, let $D_{c}\left(T_{1}, T_{2}\right)=k_{1} d^{\prime}+k_{2} d_{m}$ for any two real number $k_{1}$ and $k_{2}$, these two real number can be defined according to his (or her) requirement. When one choose $d^{\prime}$ be mutated distance and $d_{m}$ be mixture distance, the time complexity of the proposed algorithm for this compound-distance $D_{c}$ will be $O\left(n^{2}\right)$. In the future, we hope to find other metric for computing the distance with considering these two information, time parameter and set of mutated sites, between two mixture trees and it can satisfy not only pseudo-metric, but also the metric conditions.

TABLE VI
THE COMPARISON OF THE ALGORITHMS OF OUR WORK.

|  | Mixture <br> Distance [16] | Mutated <br> Distance |
| :---: | :---: | :---: |
| Modified Algorithm | $O\left(n^{2}\right)$ | $O\left(n^{2} \times \max \left\{h\left(T_{1}\right), h\left(T_{2}\right)\right\}\right)$ |
| Improved Algorithm | $O($ nlogn $)$ | $O\left(n^{2}\right)$ |

Lin, "A study on measuring distance between two mixture trees," In Partial Fulfilment of the Requirements for the Degree of Master of Science, Department of Computer Science and Information Engineering National Chi Nan University, Puli, Nantou Hsien, Taiwan, Republice of China, Juan 2008.

Wan Chian Li received her B.S. degree in Informa-
 tion science, National Taipei College of Business in 2008. Her M.S. degrees in Department of computer science and information engineering, National Chi Nan University in 2010. She is a engineer at project development Department of Innovative Center for Cultural and Creative Industries, Tamkang University.

Justie Su-Tzu Juan received her B.S. degree in applied mathematics from Department of Mathematics, Fu Jen Catholic University in 1993, her M.S. and Ph.D. degrees in applied mathematics from National Chiao Tung University, R.O.C. in 1996 and 2000 , respectively. She is currently a professor with the Department of computer science and information engineering, National Chi Nan University, R.O.C. Her research interests include graph theory, information security, cryptography, algorithms, and combinatorial mathematics.

Yi-Chun Wang received her B.S. and M.S. degree in Department of computer science and information engineering, National Chi Nan University in 2005 and 2007, respectively. She is currently pursuing his PhD degree in Computer Science and Information Engineering at National Chi Nan University, Nantou County, Taiwan. Her research interests include graph theory, algorithm and secret sharing and image sharing.

Shu-Chuan Chen received her B.S. degree in Applied Mathematics from National ChungHsin University in 1994, her M. S. degree in Applied Mathematics from National Donghwa University in 1996, and her PhD in Statistics and Operations Research from Penn State University in 2003. She is currently an Assistant Professor of Statistics in School of Mathematical and Statistical Sciences, Arizona State University, US. Her current research interests include data mining, pattern recognition, and statistical methods in genetic data analysis.
