

# Preparation and Characterization of Photocatalyst for the Conversion of Carbon Dioxide to Methanol

D. M. Reddy Prasad, Nur Sabrina Binti Rahmat, Huei Ruey Ong, Chin Kui Cheng, Maksudur Rahman Khan, D. Sathiyamoorthy

**Abstract**—Carbon dioxide ( $\text{CO}_2$ ) emission to the environment is inevitable which is responsible for global warming. Photocatalytic reduction of  $\text{CO}_2$  to fuel, such as methanol, methane etc. is a promising way to reduce greenhouse gas  $\text{CO}_2$  emission. In the present work,  $\text{Bi}_2\text{S}_3/\text{CdS}$  was synthesized as an effective visible light responsive photocatalyst for  $\text{CO}_2$  reduction into methanol. The  $\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalyst was prepared by hydrothermal reaction. The catalyst was characterized by X-ray diffraction (XRD) instrument. The photocatalytic activity of the catalyst has been investigated for methanol production as a function of time. Gas chromatograph flame ionization detector (GC-FID) was employed to analyze the product. The yield of methanol was found to increase with higher CdS concentration in  $\text{Bi}_2\text{S}_3/\text{CdS}$  and the maximum yield was obtained for 45 wt% of  $\text{Bi}_2\text{S}_3/\text{CdS}$  under visible light irradiation was 20  $\mu\text{mole/g}$ . The result establishes that  $\text{Bi}_2\text{S}_3/\text{CdS}$  is favorable catalyst to reduce  $\text{CO}_2$  to methanol.

**Keywords**—Photocatalyst, Carbon dioxide reduction, visible light, Irradiation.

## I. INTRODUCTION

DUCE to the reliance of the world on fossil fuels as a major source of energy, the carbon dioxide ( $\text{CO}_2$ ) emission to the environment is inevitable which is responsible for global warming. Photocatalytic reduction of  $\text{CO}_2$  to fuel, such as methanol, methane etc. is a promising way to reduce greenhouse gas  $\text{CO}_2$  emission and energy crisis [12]. UV light covers only 3% and visible light 44% of the solar light spectrum [10] hence visible light active photocatalyst for  $\text{CO}_2$  conversion is important.

Threats of global warming and energy crisis had accelerated the rush for new renewable energy resources. In order to reduce carbon dioxide emission and to produce sustainable fuels, recycling the greenhouse gases such as carbon dioxide seems eminently potential. Due to the increasing levels of carbon dioxide emissions from fossil fuels consumption, the problem of global warming has aroused into public concern [2]. One of the biggest challenges are to seek a renewable energy which not only meet the increasing energy demand, but also to replace the traditional chemicals fuels and

environmentally friendly. One of the prospective way to reuse hydrocarbon resources is the photocatalytic reduction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  utilizing the solar energy [12]. By using this way, carbon dioxide emissions can be reduced and energy crisis can be solved.

The most popular photocatalytic material with an excellent stability, innocuity and low price [6], three-dimensional, larger surface and regular structure [5] is titanium dioxide ( $\text{TiO}_2$ ). However,  $\text{TiO}_2$  have low quantum efficiency, which increase the combining ratio of electrons and holes. It can only absorb 5% sunlight in the ultraviolet region since it is a wide band gap semiconductor (3.0-3.2 eV) [11]. The ideal photocatalyst with a gap of 1.5 eV is well approximated by narrow band gap semiconductor material and highly stable electrodes may be produced by appropriate surface modification in order to enhance the photocatalytic activity and visible light response. CdS is a classical photocatalyst shows high activity under ultraviolet (UV) light irradiation. It is well known that the band gaps of CdS and  $\text{Bi}_2\text{S}_3$  are narrower, active under visible light irradiation and the potentials of conduction bands are more negative compare to other photocatalysts [9], [13]. The CdS and  $\text{Bi}_2\text{S}_3$  have higher quantum efficiency, which decrease the combining ratio of electrons and holes.

The photocatalytic reduction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  to reusable hydrocarbon resources such as methanol is found to be one of the prospective ways to reduce  $\text{CO}_2$  emissions and resolve the energy crisis. The process of water-splitting is a highly endothermic process ( $\Delta\text{H} > 0$ ). The minimum potential difference (voltage) needed to split water is 1.23V at 0 pH [2], [8]. Since the minimum band gap for successful water splitting at pH=0 is 1.23 eV, corresponding to light of 1008 nm, the electrochemical requirements can theoretically reach down into infrared light, albeit with negligible catalytic activity.

Inoue et al. 1979 [7] first reported that  $\text{CO}_2$  bubbled in water was reduced to  $\text{HCHO}$ ,  $\text{HCOOH}$  and  $\text{CH}_3\text{OH}$  over various photocatalysts, such as CdS,  $\text{TiO}_2$ ,  $\text{ZnO}$ , GaP and SiC under photo-irradiation of their aqueous suspension. In addition, the catalytic effect of  $\text{Bi}_2\text{S}_3$  and CdS was examined for  $\text{CO}_2$  reduction in presence of  $\text{H}_2\text{S}$  and found comparable products [1]. Similar works were also reported in the literatures and they obtained various hydrocarbon products using aqueous CdS or ZnS colloids [3], [4]. These photocatalytic reductions of  $\text{CO}_2$  over CdS and  $\text{Bi}_2\text{S}_3$  had been carried out under UV light irradiation or by other reductants, and they have not been used for photocatalytic reduction of  $\text{CO}_2$  to methanol with water as reductant under visible light irradiation. However, photocatalyst with excellent stability,

efficient, cost-effective and active in visible light region for the conversion of  $\text{CO}_2$  into methanol still suffers from lacking. In this study, a hetero-junction of  $\text{Bi}_2\text{S}_3$  and  $\text{CdS}$  was synthesized as an effective visible light responsive photocatalyst following effective hydrothermal method. In addition, the catalytic activity of the  $\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalyst was investigated for  $\text{CO}_2$  conversion into methanol.

## II. MATERIALS AND METHODS

### A. Chemicals

The chemical reagents used in this experiment were thiourea, cadmium nitrate tetrahydrate, cadmium sulfide ( $\text{CdS}$ ) powder, bismuth III nitrate pentahydrate, sodium nitrite, potassium hydroxide and sodium sulphite. All chemicals were ~99% purity obtained from Sigma, USA.

### B. Preparation of Photocatalysts

The  $\text{Bi}_2\text{S}_3/\text{CdS}$  catalyst was prepared by following direct hydrothermal method.  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  and thiourea of different compositions such as 6, 3 and 2.25 g, respectively were considered for the preparation followed by hydrolysis with 600 mL of deionized water in an autoclave at 90–100°C for 6 h. Then cooled down to room temperature and successively the precipitate was filtered off, washed with distilled water and dried in an oven at 60°C overnight. The catalyst was grinded with mortar before calcined at 250°C for 3 h. Similarly, the weight proportions of  $\text{Bi}_2\text{S}_3$  to  $\text{CdS}$  were 15%, 30% and 45% were prepared with the same method.

### C. XRD Experiment

The XRD patterns were obtained at room temperature using MSAL-XD2 diffractometer with  $\text{CuK}\alpha$  radiation (operated at 36 kV and 30 mA,  $\lambda = 0.15406 \text{ nm}$ ).

### D. Photocatalytic Experiment

The photocatalytic experiment was performed in a photochemical reactor equipped with a magnetic stirrer, a quartz cool trap and a condensation tube. A 500 W Xe lamp was located in the quartz cool trap as illuminant. The UV light was removed by 1.0 M sodium nitrite solution. Sodium nitrite, potassium hydroxide and sodium sulphite of corresponding quantities 0.7, 1.2 and 3.7 g were dissolved in 300 mL of ultra-filtered water. The solution was then put into the photochemical reactor. Ultrapure  $\text{CO}_2$  was bubbled through the solution in the reactor before irradiation for 30 min to ensure that all dissolved oxygen was eliminated. 0.2 g of catalyst powder was added into the solution and the irradiation lamp was turned on to start the photoreaction. The temperature with the range of 30–35°C was observed for every 1 h to avoid the loss of methanol into the air. Ultrapure  $\text{CO}_2$  was continuously bubbled through the solution during the whole irradiation for 6 h. A needle-type probe was inserted into the solution of the reactor with the aid of vacuum pump to withdraw a small amount of liquid samples for 1 h interval up to 6 h (Fig. 1). The concentrations of methanol in the samples were analyzed using a gas chromatograph flame ionization detector (GC-FID).

## III. RESULTS AND DISCUSSION

### A. XRD Analysis

The XRD pattern of pure  $\text{CdS}$  is shown in the Fig. 2 ( $2\theta=3$ – $80^\circ$ ), was used as a reference for the structural analysis of prepared  $\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalysts. XRD patterns of various as-prepared photocatalysts are shown in Fig. 3 corresponding to (a)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (b)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (15%) (c)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (30%) (d)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (45%).

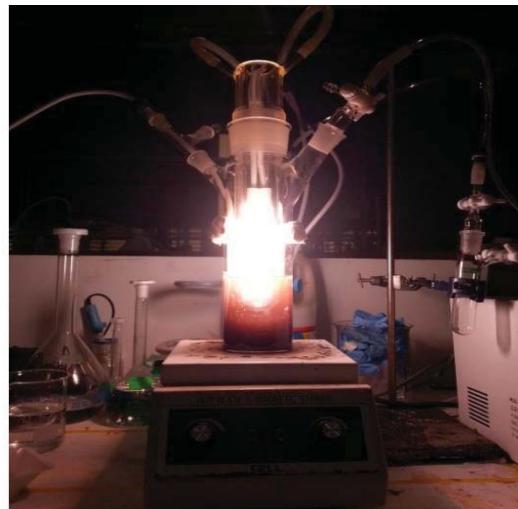

Fig. 1 Experimental Setup

The XRD patterns of the catalysts were recorded in the range of diffracting angles of  $20=3$ – $80^\circ$  but shown only  $20=15$ – $50^\circ$ , the most significant portion. The XRD study reveals that  $\text{CdS}$  (15–45 wt%) incorporation in  $\text{Bi}_2\text{S}_3$  takes place and gradual changes in the crystallographic parameters are detected. It was observed from the XRD analysis that there are mainly two types of crystallite structures e.g., orthorhombic  $\text{Bi}_2\text{S}_3$  and cubic  $\text{CdS}$ . Using Scherrer formula for the full width at half maximum (FWHM) of the main peaks, the average crystallite size of the  $\text{CdS}$  and  $\text{Bi}_2\text{S}_3$  were found to be 5–30 nm and 30–50 nm, respectively. It has been noticed that the crystallite size of  $\text{Bi}_2\text{S}_3$  increased with  $\text{CdS}$  loading. According to the standard diffraction peaks of cubic  $\text{CdS}$  (JCPDS # 89-0440), the sharp peaks were consistent with the peak positions of  $\text{CdS}$  (100, 002, 101) (Fig. 2).

It can be seen from the XRD spectrum of the  $\text{Bi}_2\text{S}_3$  in Fig. 3 that the peaks were in good agreement with the standard diffraction peaks of orthorhombic  $\text{Bi}_2\text{S}_3$  (JCPDS # 17-0320). Five peaks with  $2\theta$  values of  $25.1^\circ$ ,  $28.78^\circ$ ,  $31.94^\circ$ ,  $46.62^\circ$  and  $53.72^\circ$  in  $\text{Bi}_2\text{S}_3/\text{CdS}$  correspond to the crystal planes of (130), (211), (221), (351) and (431) of orthorhombic phase  $\text{Bi}_2\text{S}_3$ , respectively.

The lattice parameters are estimated for orthorhombic structure of  $\text{Bi}_2\text{S}_3$  and found to be  $a_0=10.84 \text{ \AA}$  (standard  $a_0=11.49 \text{ \AA}$ ),  $b_0=11.38 \text{ \AA}$  (standard  $b_0=11.30 \text{ \AA}$ ) and  $c_0=3.97 \text{ \AA}$  (standard  $c_0=3.981 \text{ \AA}$ ). Hence, it is confirmed that the  $\text{Bi}_2\text{S}_3$  structure is orthorhombic. Moreover, the peaks of all the  $\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalysts in Fig. 3 suggesting that all the

$\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalysts are all composed of the two crystallite phases and there are no unknown phases proved that they do not react each other and make a hetero-junction to show catalytic activities.

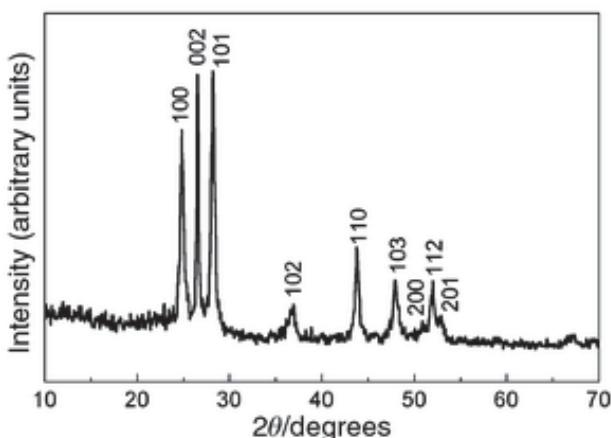

Fig. 2 XRD pattern of CdS shown as a reference

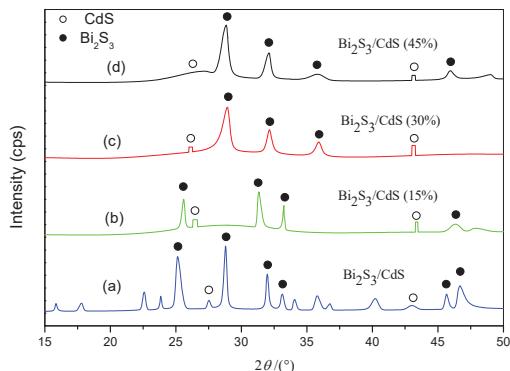

Fig. 3 XRD patterns of various photocatalysts (a)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (b)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (15%) (c)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (30%) (d)  $\text{Bi}_2\text{S}_3/\text{CdS}$  (45%)

#### B. Photocatalytic Activity

The yields of  $\text{CH}_3\text{OH}$  in the photocatalytic reduction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  on various photocatalysts under visible light irradiation are shown in Fig. 4. The presence of  $\text{CH}_3\text{OH}$  in the final samples is shown in Fig. 5. From Fig. 4, it can be seen that the generation rates of  $\text{CH}_3\text{OH}$  over the  $\text{Bi}_2\text{S}_3/\text{CdS}$  were significantly higher when the concentration of  $\text{CdS}$  was increased. The highest yield of methanol over  $\text{Bi}_2\text{S}_3/\text{CdS}$  was  $20 \mu\text{mole/g}$  when the weight proportion of  $\text{Bi}_2\text{S}_3$  to  $\text{CdS}$  was 45%. This may be due to doping  $\text{Bi}_2\text{S}_3$  to  $\text{CdS}$  could form hetero-junction structures which improves the separation of electrons and holes, prevents the charge-carrier recombination and prolongs the lifetime of photo-carriers in  $\text{Bi}_2\text{S}_3/\text{CdS}$  photocatalyst. In addition, the spread of belt-shaped  $\text{Bi}_2\text{S}_3$  on the surface of  $\text{CdS}$  particles was better when the weight proportion of  $\text{Bi}_2\text{S}_3$  to  $\text{CdS}$  was 45%. The mechanism of photocatalytic reduction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  to  $\text{CH}_3\text{OH}$  is shown in Fig. 5. It can be seen from Fig. 5 that both  $\text{Bi}_2\text{S}_3$  and  $\text{CdS}$

can be used as photocatalyst for reducing  $\text{CO}_2$  to  $\text{CH}_3\text{OH}$  under visible light.

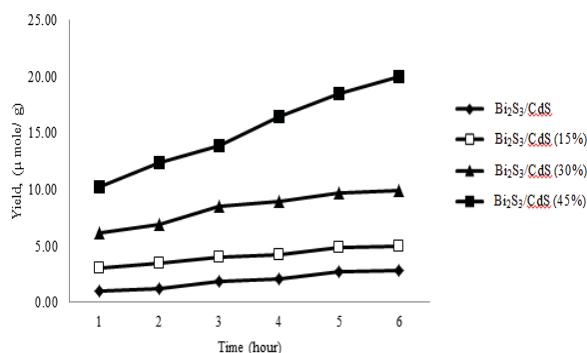

Fig. 4 The yields of  $\text{CH}_3\text{OH}$  in the photocatalytic reduction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  over various photocatalysts under visible light irradiation

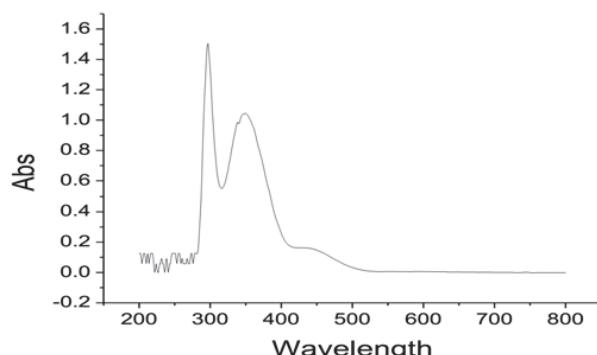

Fig. 5 Methanol detection in a sample by UV spectrophotometer

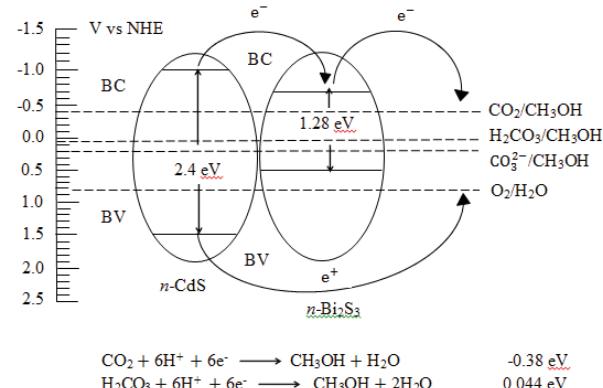

Fig. 6 The mechanism of photocatalytic reduction for production of  $\text{CH}_3\text{OH}$

This is because the potentials of conduction bands of  $\text{Bi}_2\text{S}_3$  and  $\text{CdS}$  are more negative than all those of methanol yield for. Fig. 6 that both  $\text{Bi}_2\text{S}_3$  and  $\text{CdS}$  can be used as the photocatalysts for reducing  $\text{CO}_2$  to  $\text{CH}_3\text{OH}$  under visible light. This is because the potentials of conduction bands of  $\text{Bi}_2\text{S}_3$  and  $\text{CdS}$  are more negative than all those of methanol yielded for  $\text{CO}_2(\text{g})$ ,  $\text{H}_2\text{CO}_3$ ,  $\text{CO}_3^{2-}$  etc. in water [14].

## IV. CONCLUSION

The Bi<sub>2</sub>S<sub>3</sub>/CdS photocatalyst were prepared by direct hydrothermal reactions between their corresponding salt and thiourea. The Bi<sub>2</sub>S<sub>3</sub>/CdS photocatalyst were characterized by XRD and FTIR. The modification of CdS with Bi<sub>2</sub>S<sub>3</sub> can enhance its photocatalytic activity and visible light response. The highest yields of methanol over Bi<sub>2</sub>S<sub>3</sub>/CdS photocatalyst with 15%, 30% and 45% weight proportions under visible light irradiation were 5, 9.92 and 20 μmole/g, respectively.

## ACKNOWLEDGEMENT

We would like to express our gratitude to Universiti Malaysia Pahang for providing all the facilities for our research work.
